305. Will you have the kindness to explain your view on that subject?—It seems to me that the case of snake-poisons is a very fair one by which to illustrate the absolute necessity, if there be a necessity in anything, for the performance of experiments upon animals. I believe that there are not less than 20,000 deaths from snake bites annually in India. Of course I have no personal knowledge of that, but it is often so stated. Now it seems almost impossible that an antidote for an Indian snake bite should be found except by having animals bitten with snakes and immediately experimented on to see what is likely to cure them. It is perfectly hopeless to make these observations upon the persons bitten by the snakes, because, in the case of nearly the whole of them, they are not found till either they are dead or dying and past all hope of cure: so that the only objects upon which the experiments can be employed are the animals who may at the time be bitten and be immediately observed. It may be objected that the progress of science will ascertain by other means some antidote to snake bites. I should think it would be a very low estimate to suppose that the progress of science would do it in 25 years. In the meantime half a million of persons would be killed by snake bites, and those half a million might possibly, I do not say even probably, but they might possibly, be rescued by a sufficient course of experiments performed on living animals immediately observed, and having a variety of treatments employed upon them directly they are under the influence of the snake poison. And I may add that while these experiments, as I suppose, ought to be made with substances likely to produce the desired effect, the few persons found under the influence of snake bites are treated by means altogether inadequate, and of which the inadequacy would be discovered by proper experiments. I have asked about some experiments which have been performed lately in reference to snake bites. There has been a Government-reward offered for the discovery of a sufficient antidote for snake bites in India; and some few months ago a person applied for this reward, and was referred to Saint Bartholomew's Hospital, to see whether he had really found an antidote. He was so convinced, I am informed, of the efficacy of his antidote that he professed himself ready to be poisoned with some of the cobra poison. They persuaded him to wait, and they had some pigeons innoculated with the cobra poison, which all quickly died; and as the chance was, those that had used the antidote given to them died a little sooner than those which had not, and the inventor of the antidote was persuaded not to subject himself to his own treatment. I have thought carefully over the whole matter, and it does not seem to me probable that, under any circumstances, we can suppose that short of 50 years hence a true antidote for Indian snake bites should be found by any other means than by a series of experiments which must necessarily involve the painful dying of possibly a large number of creatures, pigeons, rabbits, and others.

306. With regard to medico-legal investigations, have you anything to say on that subject?—No, I have no familiarity with them.

307. Does it at all come within your knowledge to what extent those experiments are practised in distant places, in country towns and so forth?—I have no knowledge of that, but my belief is that experiments on living animals are not performed at all, except in some schools of medicine, and by some physiologists who are not connected with schools of medicine.

308. Nor can you guide us perhaps as to whether there is really a great extent of abuse in this country on the subject?—I think there is not. I think the worst I could say of it, as I said just now, is that some observers seem to put more reliance on experiments on living animals for therapeutic purposes than I should. But they can plead that very remarkable results have come from their observations, of which results I will give you one or two examples, if you will allow me. The treatment, for example, of *angina pectoris* I believe to be now very much more nearly successful than it ever was before, and to have been discovered mainly by experiments on living animals. The use of the substance called nitrite of amyl, which has the effect of checking the agony, and probably also sometimes the mortal effects of *angina*, was a result mainly of a series of experiments on living animals. I could give you the history of the experiments if you wish, but perhaps it is enough for me to make the statement.

309. (*Lord Winmarleigh.*) Was that such an experiment as could be performed without creating pain, or was it one which necessarily created a great deal of pain to the animal?—No, I apprehend not great pain; for nearly the whole of it, if not the whole, might be done under the influence of anæsthetics.

310. Not the whole of it?—I should think the whole might be done under their influence, but I would not venture to say that with certainty.

311. (*Sir John Karslake.*) What was the nature of the experiment? Was it an external application?—Dr. Brunton found that in the paroxysms of *angina*, in a person he had to examine, the blood vessels became very tightly filled; and it occurred to him that the reason of the intense agony of *angina* might be from this excessive tension of the blood vessels. One method of relieving the tension was to remove a quantity of blood, which, however, might be injurious. Another was to find some means by which the blood vessels themselves might have their tension diminished; and among the substances which he tried on animals was this nitrite of amyl. He found that it would relieve the tension of the blood vessels, and by relieving them would put an end to or mitigate the paroxysms of agony which occur in angine.

312. (*Lord Winmarleigh.*) Will you state the process?—It is all published, and if you would allow me

Sir J. Paget, Bart.

5 July 1875.

I will send the Commission an abstract of the paper. It would require the exposure of blood vessels in the living animals, and the testing, with apparatus adjusted for the purpose, of the amount of pressure exercised by the blood on the interior of the vessel.

313. (*Chairman.*) All of which might be done under the influence of chloroform ?—Yes.

314. (*Lord Winmarleigh.*) And it could not have been done by any experiments on the human body ?—Certainly not.

315. (*Mr. Hutton.*) But does not chloroform very much alter the action of the heart, so as to render experiments of that kind uncertain ?—Not so much as to affect an experiment in the hands of a careful observer, who would first test the pressure of the blood while the animal was under chloroform, and then see whether it was diminished by the administration of nitrite of amyl or anything else.

316. (*Lord Winmarleigh.*) In all the different hospitals and colleges is there a school of physiology attached ?—There is not a separate school of physiology. Physiology is taught as one of the branches of study; and now there is adjacent to the hospital what is called a physiological laboratory.

317. I observe in the contract for buildings at Edinburgh that the contractor states to the promoters of the hospital that he has arranged a chamber for a school of physiology expressly for that purpose, in which he has made arrangements for animals, and for the experiments which are made upon animals; is that a common thing ?—Yes; but I should be sorry for it to be supposed that a physiological laboratory is for nothing but experiments on living animals. It includes a large quantity of work with which living animals have nothing to do; for example, all the microscopic teaching.

318. I am aware of that; but this contractor states that he has made arrangements for living animals; that he has made a provision for dogs and other animals. Now is that an exceptional case ?—That, I should think, is very much beyond what would be found in any school in London; certainly I can speak of Saint Bartholomew's, and by repute of some of the other larger hospitals, and no arrangement is made in them for living dogs.

319. How is the study carried on, for instance, in one of our principal London hospitals ?—It is carried on mainly through teaching by the use of the microscope upon dead textures, and some few living parts, such as the web of frogs, by showing such processes as those of artificial digestion; by testing blood and other fluids chemically; and sometimes by exhibiting experiments on animals kept insensible.

320. But now supposing that a school of physiology for experiments on animals is established at a hospital, who would be the parties in one of our great colleges who would be allowed to make all these experiments at the present time ?—At present it would be left entirely to the discretion of the lecturer on physiology. Therein I think may be an error. I think that in any case where courses of experiments on living animals are to be performed for the purpose of teaching, whether in the school of physiology or materia medica, or any other, no such experiments should be done except with the consent of a committee of medical officers and lecturers, or even, if it were thought proper, some of the governors of the hospital.

321. And do you think that it would be possible to limit these experiments by regulations in the hospital such as you have described ?—Yes.

322. And to forbid them in all other parts ?—Yes.

323. You would not, for instance, allow a body of surgeons in a town like Birmingham to conduct operations of that kind without some control such as you have described ?—There is a medical school at Birmingham.

324. Then I will take some town where there is not a medical school, that is what I wanted to get at. You would not allow these experiments to be made by any body of the medical profession, unless under some control such as you have described as what should be exercised in these principal hospitals ?—I think it might be safely left to members of my profession. I think it is unreasonable to suppose that any three or four persons of my profession would agree to an unnecessary or unreasonable course of experiments. One person in his zeal might do an unwise thing, but four certainly would not.

325. Can you state as to all the hospitals that no person of less authority than the person you have described would be allowed to make experiments ?—I cannot speak from knowledge of it, but I should have the strongest conviction that if it is done it is done secretly.

326. At any rate you think it ought not to be done ?—It certainly ought not to be done, except by persons in authority; and I think it would be satisfactory that for experiments to be done on living animals there should be a committee of the medical officers and lecturers of the hospitals or schools, before whom an outline of the course of experiments should be laid for their decision as to whether they were reasonable or not.

327. Do you think it would be unreasonable to say that no experiment should be made on a living animal, unless it were stated to some authority beforehand that some experiments were about to be made ?—I think it would be an unreasonable rule in the case of persons thoroughly conversant with the manner of making experiments, for they would be better judges of the propriety of them than those to whom the question would be submitted.

328. An opinion has been expressed here that it would be advisable to have an officer for these experiments corresponding to the inspector of anatomy, without whose authority they should not be performed; that is to say, that there should be a license given by this inspector to persons to perform these experiments ?—If you mean in the same manner as every anatomical teacher now, in order to have the bodies of the dead for dissection must have a licence, I think there is no objection to that; if there is any legislation at all I should think it must take that form.

329. And you think that no experiments should be made except by a person so licensed by some authority ?—If there is to be legislation at all. That of course it is not for me to decide: my impression is that public opinion will accomplish all that is necessary.

330. Without legislation ?—Without legislation; but if there is to be legislation, I think it must take that form, that no person shall be allowed to perform experiments on living animals, unless licensed as the teachers of anatomy are now licensed to have the bodies of the dead for dissection.

331. What are the regulations with regard to the bodies of the dead ? It is not all done under licence, is it ?—Yes; every teacher of anatomy in a medical school requiring bodies for dissection, not for ordinary examination after death, but for dissection, must be licensed for that purpose by the Secretary of State for the Home Department.

332. Do you think that law is rigidly observed ?—Yes, rigidly. It involves the whole process of the burial of the body; bodies may not be brought to the schools except under that licence, nor removed from them except with the authority of the person holding the licence.

333. (*Sir John Karslake.*) What is the case with reference to private practitioners ?—No private practitioner can have a body for dissection.

334. Cannot he under any circumstances ?—No.

335. (*Mr. Erichsen.*) And never does ?—No.

336. (*Sir John Karslake.*) Now the question has been put to you whether, in the event of legislation being suggested at all, it would be expedient to have licenses given by the Home Secretary, who would have some persons in authority to confer with, as to whether the person applying for the license was competent to hold the license or not. Should you think that advisable, having regard to the necessity that may occur for making an experiment upon an animal, with a view to a difficult operation on a man ?—Yes.

Sir J. Paget, Bart.

5 July 1875.

I think in the case of teachers of anatomy it is requisite to have the signatures of two magistrates; I think something of that kind would be required.

337. But supposing a private practitioner about to perform a delicate operation on a man living in the country thought it absolutely necessary, with a view to perform the operation satisfactorily, to make an experiment on a living animal, should you think that he was justified in doing that?—I quite think that he would be justified; and that is one of the hindrances which I think legislation would put in the way of necessary knowledge.

338. Do you think that the case I have put is a case which might occur frequently in private practice?—No, not frequently, but occasionally.

339. And in those occasional cases it would be absolutely necessary to resort to that experiment on the animal with a view to carry out an experiment satisfactorily on the human being?—Yes.

340. That is the reason why you think that legislation on the subject would be inexpedient?—I think it would be a great hindrance to some useful measures; and the case you have cited is a case in point.

341. Public opinion would prevent the practice of vivisection from being carried on to an extravagant or improper extent?—Yes.

342. I suppose in the schools of surgery dead animals are very little used for the purpose of anatomy?—Very little.

343. It is almost entirely on the human being?—Yes.

344. And that therefore the cases in which it would be required to have a live animal under the knife at all, or under poisons, for the purpose of carrying out investigations as to the use and character of poisons, are comparatively very rare?—Very rare.

345. In your judgment, so far as you can have any experience in the matter, is the practice increasing to any great extent now?—I do not believe it is. In one direction it may be increasing, namely, in the inquiry into the influence of poisons and of supposed or real medicinal substances. In the other direction, that of mere physiology and of experiments for what may be called surgical purposes, such as tying of arteries, transfusion, division of tendons, fractures, and the like, I should think it is very much diminishing.

346. And that notwithstanding the absence of pain caused by anæsthetics?—Yes. I think it may be generally held that most of the facts on those subjects have been already ascertained, and that there is no advantage in repeating experiments.

347. And that the medical profession generally do not think it necessary to repeat experiments, because of what has been ascertained already?—Yes.

348. (*Mr. Hutton.*) Do you mean to say that this process of physiological investigation is not very much increasing as compared with what it was in Sir Charles Bell's time, for instance?—It has very much increased since Sir Charles Bell's time.

349. And he speaks of that as being already to a monstrous extent prevalent?—I think he must at that time have been speaking almost entirely of the French School of Physiology. Majendie was at that time the principal teacher. I should not like to mention Majendie's name with entire reprobation (as I have heard it mentioned), because he really accomplished a very large work and an excellent one, which has guided us to a great deal of knowledge, which, except for his experiments, could not have been ascertained. I quite think that his experiments were very needlessly repeated, needlessly shown to classes of students who could have profited nothing by them; but the knowledge which we have acquired by them has been very useful, even for saving human lives.

350. Do you not think that the mere fact that a laboratory has been proposed at Edinburgh with an engine at work for constantly keeping up artificial respiration in animals indicates quite a new era as it were in British medical schools?—I do not know really what the experiments for which the laboratory in Edinburgh is to be fitted up might be; and I quite think it is possible that they are developing the school of physiology unnecessarily in the direction of experiments on living animals; but it may be said in a general way, that the better the apparatus you use, although it may be large and cumbrous, the less is the pain that you inflict. Physiological experiments may be done under anæsthesia, but if the anæsthetic is not well given the animal gets out of its influence; therefore I should not blame anyone who had the design for performing experiments under anæsthesia for having all his apparatus very costly and complete.

351. Are not the schools at Leipsig, Vienna, Paris, and Florence, and others, all of them schools visited by our own medical men? They come back with these new methods in their heads, which they are anxious to apply for the purposes of teaching here?—Nothing imported from any of the schools you mention is commonly employed in the schools here.

352. Now Doctor Pye-Smith uses, even for the purposes of demonstration at Guy's Hospital, I think, living animals, and defends that practice?—I do not know whether he does; I could only speak certainly of St. Bartholomew's, where I think it is never done; unless on living animals that are completely anæsthetised, or a turtle, for instance, with his head removed.

353. But he is hardly a living animal?—Yes, except for the purpose of sensation. He has none with his head off, but many living actions go on and can be observed in him.

354. Do you know this handbook of Doctor Burdon Saunderson's?—Not well.

355. A large number of the experiments mentioned in it are not experiments under genuine anæsthetics at all?—I know enough of that book to make me believe that it must have been written for persons well instructed in physiology already, but anxious to make further inquiries in it. I should think such a book as that would never be used by students.

356. It is said to be specially for the use of students?—Not what I should mean by students; but for persons diplomatised, for instance, and still studying physiology.

357. You say that by far the greater number of these experiments can be made under anæsthetics. I find that exceeding few of these are even suggested to be performed under anæsthetics; and I have heard the opinion of physiologists that for the lower animals anæsthetics are not available; the frog is killed by chloroform?—As to the lower animals, there comes in a separate question as to the degree of their sensibility. My impression is that they are extremely little sensitive; and certainly with regard to a large number of them, although they may not use anæsthetics on them, the greater part of the experiments may be very well done after their brains are removed. A frog, for instance, will serve for nearly all the experiments you want to try on him after you have beheaded him.

358. In studying, for instance, inflamed tissues, they are obliged to keep the animal alive in order that the tissue may inflame; are they not?—But the inflamed tissue of a frog may be examined without the infliction of more pain than a casual scratch on one's hand.

359. As a matter of fact, these experiments are described as lasting for a couple of hours; and it is stated to be necessary to keep the animal alive for a couple of hours?—The pain is really nothing in the examination of the tissue of a frog's web.

360. In the case of the inflamed tissue of a frog's eye, would that be so?—That is more difficult of use; but you may examine the whole process of inflammation of the web without inflicting more pain than would come from an ordinary pustule on one's skin.

361. In a great many of these cases of the tissues of mammalia they are inflamed during life, are they not?—I have never performed experiments of that sort, and I would not venture to say how far they are necessary.

Sir J. Paget, Bart.

5 July 1875.

The only experiments of the kind that I have performed on warm-blooded animals were on the transparent wings of bats; and in those you may see the process of inflammation completely with not more pain than is caused by dropping hot sealing-wax on your own finger.

362. That is guess work, is it not?—I know what a drop of hot sealing-wax on my finger is; and I should do the same with a bat's wing.

363. I find that there are experiments, lasting a long time, on the arterial system, for the purpose of noting the curve or the curves of the arterial waves. It appears that the ordinary anæsthetics are inapplicable for that purpose; that they affect the action of the heart so much that curare is the only one applicable; and Claude Barnard states that that only paralises the motor system, and leaves the suffering the same. That class of experiments you would regard as a painful class, would you not?—I should regard those as amongst the experiments that ought never to be repeated. Experiments for the purpose of repeating anything already ascertained ought never to be shown to classes, and ought never to be made, except on a reasonable expectation of discovering something new in physiological knowledge. I think those are experiments that should be strictly limited.

364. Where would you put your limit about the object of an experiment; should it be simply scientific?—I think you must put your limit in the reason of the person experimenting, and that he must be sole judge.

365. Then as all investigations suggest new ones practically the higher the scientific mind the more the number of experiments that would suggest themselves to it that might be performed with useful scientific results, I suppose?—I could not say that the number would necessarily increase; because the higher scientific mind would probably deduce from a few facts more accurate conclusions than the lower one would from many; but, knowing the general humanity of scientific men, I think they may be left to be fair judges of what amount of pain it is reasonable to inflict for the sake of attaining some useful knowledge.

366. (*Chairman.*) That assumes, does it not, that these experiments are only to be performed by persons of a high scientific character?—Certainly; I think that no others should perform them.

367. If veterinary surgeons and others in country towns operate themselves in experiments of this kind we should be justified in preventing that?—Yes.

368. Now coming up to high scientific names,—Majendie's is a high scientific name; but still the important results which you have attributed to him might have been ascertained with a less degree of suffering to animals if the experiments had been in the hands of some other persons?—Yes.

369. (*Sir John Karslake.*) Would that have been so with regard to the principal experiments performed by Majendie, (I am not speaking of the repetition); was any unreasonable pain inflicted by him considering that at that time there were no anæsthetics?—I think he had a rough way of experimenting; he seemed really quite indifferent to pain.

370. And, in fact, he never made any secret that he was indifferent to pain?—No, I think not.

371. And disgusted people very much by showing contempt for the pain of animals?—Yes.

372. But still many of the experiments made by Majendie were made so successfully that it was unnecessary to repeat them?—Yes.

373. So that science has gained something by those experiments, however cruel he may have been in the execution of them?—Yes.

374. (*Chairman.*) And the same amount of gain to science might have been obtained without that scandal to humanity which unfortunately attaches to his name?—Yes.

375. (*Lord Winmarleigh.*) Do you believe when you come to teach a class it is possible to teach that class as well without experiment as with?—Certainly, generally it is. There are some things which it is very hard to teach unless you can show the very thing. Taking the case I mentioned, of the action of the heart for instance, I do not think that anyone could understand how a heart moves and propels blood if he did not see it, and that is one of the cases in which I should say that living animals may justly be used, because they can be used without the infliction of pain, and immediately the experiment is over they can be killed. They can therefore be killed without the infliction of any more pain than would be inflicted if they were killed for food, or as vermin, or for any other reason.

376. How long would that experiment take which you describe with reference to the heart?—With artificial respiration you could show that, I should think, for 20 minutes or half an hour, without any infliction of pain.

377. And the anæsthetics would last the whole of that time, would they?—Yes, quite well.

378. You can renew the application I suppose?—Yes, you can keep up the effect of the anæsthetic for that or a longer time.

379. (*Mr. Hutton.*) You know, I suppose, nothing about the experiments at Florence, or Leipsig, or Vienna, or Paris?—I know nothing of them.

380. (*Chairman.*) Is there anything else that you would like to add?—I have been thinking over the matter since your Lordship was so good as to talk with me about it, and it has seemed to me that it is very advisable that it should be known how much experiments on living animals contribute to knowledge, without being of themselves the sole means by which it can be ascertained; that they really stand in the place of what would otherwise be very serious experiments upon the human subject; because all our knowledge of surgery and of medicine is progressive. We find, for instance, what we expect to be a sufficient means of cure; but we find, as soon as we begin to use it on the human subject alone, that something is omitted, that some condition was overlooked or never could be discerned; and then comes in the great advantage of experiments on animals to correct our observations. Thinking what instances I might state, the one of the transfusion of the blood has seemed a fit one. I believe the use of the transfusion of blood was discovered entirely from experiments on animals. I think it never occurred to any man that if a person was bleeding to death he should bleed some one else, and restore the lost blood. The first experiments were tried by transfusion from one animal into another and then into man, and a long course of experiments were performed which have shown us this, that transfusion of the blood may certainly save the lives of a considerable number of persons who would otherwise die. It is therefore now resorted to in every necessary case: but of course the experiments on animals led to a great many precautions being found necessary, the overlooking of which would be fatal in the case of man. For example, if in transfusing blood you inject any quantity of air the patient then and there dies; and that could never have been ascertained except by experiments on animals, where the injected air was seen with the blood, and all its effects carefully traced out. Again, if during the transfusion of blood the blood clots, and clots are injected into the vessel instead of the liquid blood, death may ensue; and the manner of preventing the clotting could never have been ascertained except by experiments on living animals. So that I think, looking at those difficulties, you may be quite certain that the practice would have been given up long ago because of its killing people, if it had not been that the means of preventing death were ascertained by experiments on living animals. And there is one other case which I should like to mention, because it so chances that it concerns the last case of experimenting on animals which I had to do with. Some years ago there was a committee of the Medico-Chirurgical Society for investigating the effects of

Sir J. Paget, Bart.

5 July 1875.

anæsthetics; and one object was to determine the means by which the occasional fatal effects of chloroform might be averted. Of course in that case the observations were made on animals put under the influence of chloroform and allowed to die. The end of that course of observations was to find out that we have no certain means by which the fatal effects of chloroform can be prevented. I believe that from 20 to 30 persons die of the effects of chloroform every year in the British Islands alone; I have seen four die of it, and because of that for the last three years I have never had chloroform administered. I have gone back to the old invention of ether, which is very much less dangerous than chloroform. But there are troubles connected with it; ether is so bulky and difficult of administration and carriage that it cannot be used in military service; sailors and soldiers have to be provided with chloroform for operations on them. We therefore are still very much in want of an anæsthetic which should have the convenience of chloroform and the safety of ether. Now we cannot get that unless we try the effects of anæsthetics upon animals and let them die, and see how they die, and then see how their deaths may be prevented.

381. Those animals that die under anæsthetics do not suffer pain, do they?—No other pain than the distress of taking the anæsthetic and the premature death.

382. (*Mr. Hutton.*) It seems to me that you are using the term vivisection in a sense very much short of that in which the new school of physiologists are taking it, who make it a great means of studying the tissues in various morbid states in living animals, and almost the only means?—There must be reason and moderation in the use of these experiments. I can quite believe that ardent physiologists put more trust in the experiments on living animals than I should; and certainly those studying therapeutics and diseases think more of them than I should. I think more of the advantage of clinical inquiry. But I am very anxious that there should not be a general condemnation of experiments on animals, since it seems to me that there are a number of things absolutely essential for the life of man that cannot be ascertained by other means.

383. (*Chairman.*) And do you think that all those things might be secured with comparatively very little suffering to animals?—There is in many of these experiments the suffering of sickness which is inflicted on animals; but the inducement to perform them is very great. Members of my profession, who are constantly in the presence of persons suffering and dying from diseases that we cannot yet cure, cannot resist the temptation of endeavouring to ascertain the means of cure by any possible means, even though those means may inflict upon animals the same sicknesses as we try to cure, and try in vain to cure, in man.

384. But still anything like that amount of abuse which you have so justly reprobated is entirely beside the question?—Yes.

385. And any measures which it might be proper to take to render such abuses impossible would have no effect in limiting the amount of knowledge which you desire to see obtained?—I hope not; but they would need to be carefully adjusted to prevent that result.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Tuesday, 6th July 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
Sir J. B. KARSLAKE, M.P.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

Mr. W. Sharpey, M.D., LL.D., F.R.S.

6 July 1875.

MR. WILLIAM SHARPEY, M.D., LL.D., F.R.S., called in and examined.

386. (*Chairman.*) I think that for more than 30 years, beginning with the year 1836, you were professor of physiology in University College?—Yes, I was.

387 And you have been long secretary to the Royal Society?—Very nearly 20 years.

388. And you are conversant with the subject for which this Commission has been appointed?—Yes.

389. You have sometimes practised experiments upon living animals?—Certainly.

390. Have you ever exhibited them?—Rarely; but I have exhibited experiments on living animals.

391. But the practice of exhibiting them has been rare, I understand you?—It has been rare; it has been rather exceptional.

392. Do you consider that anæsthetics have made a great change in the question which we are appointed to consider?—A very great change indeed, inasmuch as a great many, indeed most, physiological experiments on living animals may in that way be carried on without inflicting any pain whatever to the animal.

393. Is it your opinion that such experiments are necessary?—I think they are absolutely necessary for the progress of the science of physiology.

394. Will you be so good as to illustrate that opinion?—To take the case of the motion of the blood; Galen proved by vivisection that the arteries naturally contain blood, and not air or vital spirits, as was imagined before his time. Then Harvey, as everyone knows, discovered the true motion of the blood. That was also by vivisection. He exposed the heart in various living animals of different kinds, and watched the changes that the organ undergoes in its action, and studied very carefully the motions of the heart (this must not be forgotten), and the manner in which it impelled the blood, and he then traced the course of the blood along the arteries and its return by the veins, and established in fact the doctrine of the circulation of the blood as now received. That was done largely by vivisection. It is quite true that Harvey told Robert Boyle (in the only conversation which Boyle says he ever had with Harvey), that he was led to distrust the existing belief of the course of the blood by considering the arrangement of the valves of the veins. It was plain, he said, that the common doctrine then received that the blood moved to and fro in the veins outwards from the heart and back again was incompatible with the fact of the direction of the valves, which were so placed that the blood could only move in one direction, or back towards the heart; and Harvey insists on this in his remarkable work,—small in bulk, but very great in importance —on the circulation of the blood. But while he refers especially to the arrangement of the valves as a proof of the motion of the blood in the veins, that by no means constitutes the whole doctrine of the circula-

Mr. W. Sharpey, M.D., LL.D., F.R.S.

6 July 1875.

tion. A main object was to show that the blood which returned by the veins was really the same blood, changed no doubt in its progress, but the same blood substantially that passed out by the arteries, and that he showed by vivisection. And I have thought it well to make an extract from his work, showing the fact that he had established his doctrine by vivisection on a variety of animals. Harvey knew that the blood passed from the arteries into the veins, but he could not tell by what channels it got from the one to the other; that was uncertain; and he very properly and philosophically did not attempt to determine a question which he had no means of thoroughly investigating. That was reserved for Malpighi, who made use of the microscope, and showed in the transparent parts of cold blooded animals, frogs for instance, the existence of capillary vessels between the arteries and veins through which the blood passes. Now in that way the true course of the blood was established, and also the operation of the heart; because although previously to Harvey's time the heart was recognized as a muscle, its mode of action was not understood and it was not known as a propulsive organ, whereas he proved that it really acts as a propelling organ, and drives the blood out of its cavities. The next step in reference to the physiology of the motion of the blood was made by Stephen Hales. He was a doctor of divinity, and a clergyman, not a medical man; he was the incumbent of a parish known very well to us all, Teddington on the Thames; he was a great experimenter in different ways, physical, chemical, and physiological, and, by experiments on horses and other quadrupeds, he ascertained and measured the pressure of the blood in the vessels. And that was carried out much further in our own time by improved apparatus, chiefly by Poiseuille, and by Ludwig who introduced the method of recording graphically the pressure of the blood. Then arose the question of the time taken for a portion of the blood to make the round of the circulation, and that was established by experiments on animals,—horses, dogs, sheep, and various others. The time was found to be different in different animals, and an inference was drawn by comparison as to the rapidity of the circulation in man; it turned out to be a great deal more rapid than was ever apprehended before. The rate of motion of the blood in particular vessels was more recently determined, as, for instance, in the carotid artery and other arteries of the body, although our knowledge of that is by no means so complete. That, I think, might suffice as to the motion of the blood. I should like to read this extract from Harvey's work. It is from a translation. I would have brought the original with me, but I did not suppose that it would be required: "Since, therefore, from the foregoing considerations, and many others to the same effect, it is plain that what has heretofore been said concerning the motion and function of the heart and arteries must appear obscure or inconsistent, or even impossible to him who carefully considers the entire subject; it will be proper to look more narrowly into the matter, to contemplate the motion of the heart and arteries, not only in man, but in all animals that have hearts, and further by frequent appeal to vivisection and constant ocular inspection, to investigate and endeavour to find the truth. When I first gave my mind to vivisections, as a means of discovering the motions and uses of the heart, and sought to discover these from actual inspection, and not from the writings of others, I found the task so truly arduous, so full of difficulty, that I was almost tempted to think with Fracastorius, that the motion of the heart was only to be comprehended by God. For I could neither rightly perceive at first when the systole and when the diastole took place, nor when and where dilatation and contraction occurred, by reason of the rapidity of the motion, which in many animals is accomplished in the twinkling of an eye, coming and going like a flash of lightning, so that the systole presented itself to me, now from this point, now from that, the diastole the same; and then everything was reversed, the motion occurring, as it seemed, variously and confusedly together. My mind was therefore greatly unsettled, nor did I know what I should myself conclude, nor what believe from others. I was not surprised that Andreas Laurentius should have said that the motion of the heart was as perplexing as the flux and reflux of Euripus had appeared to Aristotle. At length, and by using greater and daily diligence, having frequent recourse to vivisections, employing a variety of animals for the purpose, and collecting numerous observations, I thought that I had attained to the truth," &c. There is another large branch of physiology, that relating to the nervous system, which has been immensely advanced by vivisection. In the first place, there is the determination of the sensory and motory functions respectively of the posterior and anterior roots of the spinal nerves by Sir Charles Bell. He, besides reasoning on the subject, performed experiments on animals, one of which was when the animal was still sentient and conscious, but others were on animals that were stunned, and therefore the experiment was indecisive. He showed, it is true, that the anterior roots were motory, but it was not at all proved what were the functions of the posterior roots, except on the principle of exclusion, that as the whole nerve was sensory as well as motory, and as the anterior root was the motory root it might be presumed that the posterior root was the sensory root; but this was afterwards proved by Magendie, in a perfectly decisive experiment that was performed by him, in which, by cutting the posterior roots of a certain number of those nerves, he destroyed sensibility in a limb, whereas by cutting the anterior roots and leaving entire the posterior roots, he destroyed the power of motion and left the sensibility. After that was settled there was no occasion for further experiment. Then the functions of certain nervous centres, as for example, the spinal cord, the medulla oblongata, have been made out, so far as known, by vivisection; and so also with the functions of the different parts of the brain, though there is a great deal yet to be desired in respect to that, for we are very uncertain about the functions of particular parts of the brain itself; and I must say that much sound doctrine upon that question may be derived from pathological observations in the human subject. But there is a very broadly influential doctrine in the physiology of the nervous system, that of the reflex function, which has been largely made out by experiments on animals, and especially as regards the parts of the nervous system concerned in the production of reflex acts. That has been a most influential doctrine in physiology, and also in relation to the investigation of disease, particularly convulsive diseases,—but no doubt some practical physician can speak more fully upon that point than I can. Moreover, the functions of particular nerves have been ascertained by vivisection. Sir Charles Bell was thus enabled to point out the respective functions of the two principal nerves of the face; and I have no doubt that a member of the Commission here, Mr. Erichsen, could tell us that in former times there was a surgical operation for cutting a nerve of the face for tic doloreux, which nerve turned out not to be a sensory nerve at all. That practice has been exploded in consequence of the results of the experiments of Sir Charles Bell and Herbert Mayo. Then there is a very important nerve, the pneumo-gastric nerve, which, with the part of the brain connected with it, the medulla oblongata, plays a most important part in regulating the movements of respiration. That could only have been made out by vivisectional experiments. It also controls the movement of the heart; by the excitation of that nerve the heart is stopped and recovers again. That is the nerve too that supplies the nerves of the voice; as was known to Galen, and learnt by him through vivisectional experiments on animals.

Mr.
. Sharpey,
D., LL.D.,
F.R.S.

July 1875.

Again, while certain nerves depress the heart's action on being stimulated, others increase the heart's action; and as to the mode of their excitation, whether direct and immediate through stimulaus originating in the nervous centres, such as a mental stimulus,—or whether indirect through reflex stimulus,—those questions have been determined by vivisection; and it cannot be doubted that all that must have a very important influence indeed on the progress of medical science. There is still another very important discovery which I should mention, and that is with regard to the operation of certain nerves going to the arteries, which now go by the name of the vaso-motorial system of nerves. Through means of these the blood vessels may be narrowed and their capacity diminished when the nerves are stimulated into action; and on the other hand, when they are paralyzed the vessels are distended by the force of the blood driven from the heart; and this has an important effect in modifying the distribution of the blood; because, although the heart is the great central moving power, the alterations in the circulation in particular parts, and modifications of the rapidity in different parts, are all more or less effected through these vaso-motorial nerves. Not only has the influence of these nerves been discovered by vivisection, but also the part of the great nervous centre on which they are dependent, the medulla oblongata; the fact of that dependance has been discovered by vivisection. And again, these nerves may be influenced mentally, as in blushing, which by the way was wrongly interpreted formerly altogether. I remember that Sir Charles Bell gave the increased size of the vessels in blushing, and their fulness of blood as an example of the increased action of the arteries in driving on the blood. It turns out to be just the reverse, inasmuch as it is owing to a paralysis of the nerves governing the muscular coat of the arteries, by which their muscular power is weakened, not augmented. It is simply like the opening of a sluice, which can, of course, have no effect upon the force moving the fluid, but simply allows a greater quantity to go through. There are other examples of the value of vivisection in physiology, in what relates to the respiration. The movements of respiration; the effects of the suppression of respiration, producing what is called asphyxia; the mode in which the functions of the brain and the motion of the heart are arrested in such case; and the methods of resuscitating animals or individuals that have been suffocated; all that has been investigated through experiments on living animals. Again, I may mention that the importance of the red part of the blood, in combining with certain gases and transporting them from the lungs to the tissues of the body, and thus operating on the tissues, has been made out by experiments on animals; and the effects of noxious gases upon the blood, and the manner in which they occasion death, as for example carbonic oxide, have been ascertained by investigations on living animals, taking recent blood from animals. These are the chief illustrations that I think it desirable to adduce. Some of them do not bear directly upon the practice of medicine and surgery, but I think that is not what I should be inclined to view as the most important aspect of vivisection. I think that vivisection is of value as promoting the science of physiology; and that again is one of the great foundations of all rational medicine. I do not think I need urge upon the Commission what must occur very naturally to them, that, as the practice of medicine consists in investigating and watching the disordered conditions of the actions that occur in living bodies, and the source of these alterations and perversions, their consequences and the methods of obviating them, it is plain that, in order that such investigations may be successfully pursued, the knowledge afforded by physiology of the mode in which these actions are carried on, naturally in a healthy body, is, if not essential, at any rate highly desirable. It puts a lamp, so to speak, into the hand of the physician when he is studying disease. But there are a few cases (although I will not insist particularly upon them) in which experiments on living animals have been directly applicable to the healing art, to improvements in medicine and surgery. For example, it is well known that the different steps in the movements of the heart are indicated externally by certain sounds. Now the physician gains information as to the condition of the heart in disease by watching the changes that have taken place in these external signs by means of the stethoscope and in other ways. It is quite essential that the true relation of such external signs to the actual internal phenomena that occur should be established; and that has been the subject of various inquiries through vivisection, promoted for instance by the British Association for the Advancement of Science, and reported to the association— that is one case. To take another— the surgery of the arteries—the feasibility of tying some of the larger arteries in man was first ascertained by preliminary experiments on animals. And again, a very important inquiry took place early in this century by Dr. Jones as to the process followed by nature in checking bleeding. All this was carefully studied in a series of experiments, and was of much importance in surgery with reference to the treatment of wounded arteries and the effects of ligatures upon arteries in securing them, and Jones (Mr. Erischen will correct me if I am wrong; I have not recently looked at the point), if I remember rightiy, showed the disadvantage of using what at first sight might appear the safest kind of ligatures, large ligatures which were preferred for fear of cutting the vessels. Jones showed that a ligature should be so applied as to divide the internal and middle coats of the artery, and that the desired result of permanently closing the vessel was greatly secured in that way. With the coarse ligature there is a great risk of ulceration of the vessel, and of bleeding from it. That was another case of direct application to the healing art of the results of vivisection. And there is another kind of process to which I may refer, the process of the reparation of bone after injury and disease. In the last century there was an Italian experimenter, Michael Troja, who showed the influence of the periosteum in reproducing bone after portions had been removed or had died; and since then experiments were made by the late Mr. Syme, of Edinburgh, which are related in the Transactions of the Royal Society of Edinburgh, in which he showed the power of the periosteum in reproducing bone. But since then the investigation has been carried much further by Dr. Ollier, of Lyons; and he has shown in a very remarkable way the property of the periosteum, even when removed from the bone, and transplanted to another part of the body, of producing bone; and the results of these inquiries have been applied to the treatment of injuries and diseases of the bones and joints, with great success. There may be other cases that do not occur to me at this moment; but, as I said before, I should lay less stress upon the direct application of results of vivisection to the improvement in the art of healing than upon the value of these experiments in the promotion of physiology as a science.

395. The discoveries of Harvey for instance, and the discoveries of Sir Charles Bell, have been followed by important medical consequences?—Certainly.

396. Regarded by those investigators as scientific experiments at the time, the particular medical or surgical consequences that would result were not foreseen by them?—They were not.

397. But those consequences have nevertheless followed?—Yes.

398. And it is your opinion that the importance of experiments of this kind for scientific investigation is very much greater than for any direct medical or surgical results?—Decidedly. I believe the influence of physiological knowledge upon medicine is one that may not be very conspicuous, but it is not the less true. It operates perhaps impalpably sometimes upon the mind of the practical physician. In short, I should say

Mr. W. Sharpey, M.D., LL.D. F.R.S.

6 July 1875.

that physiology is not to be compared to the reaping machine, but rather to the plough.

399. The general proposition that scientific investigation is important for the development of medical and surgical improvement is the proposition on which you insist ?—Clearly.

400. Such investigation, I presume, will be useful in proportion as it is carried on by persons of eminent scientific knowledge and attainment ?—Most decidedly.

401. And, therefore, its principal use is limited to those competent persons like Harvey and Sir Charles Bell, and other persons of that kind, who already possess a very high amount of scientific knowledge ?—Yes; it is clear that it must be carried on by persons who are instructed.

402. And unless carried on by highly instructed people it will be comparatively valueless ?—All experiments that are made without a clear perception of what it is desired to learn, and without some experience in the methods of experimenting, are of little or no value; mere random experiments are of no use.

403. You would consider them to be mere purposeless cruelty ?—Mere purposeless infliction of suffering.

404. When Monsieur Magendie had proved the distinction between the motor and sensory nerves more completely than Sir Charles Bell had proved them there was no need of any further proof ?—No.

405. Therefore, any further experiments for that purpose would be a purposeless infliction of pain ?—Quite so. While a doctrine is being established it may require verification, and in that way to a certain moderate extent a repetition of experiments before skilled persons; but once such facts are fully established, I do not think it justifiable to repeat experiments causing pain to animals; such experiments as those of Magendie on the nerves for example ought not to be repeated when the fact has been once fairly established.

406. You said just now that some of the things which have been proved by experiments upon animals might also be deduced from pathological observations on the human patient in the hospital ?—No doubt; but then the knowledge derived from experiments on animals is of great aid in interpreting the results of observations on disease in hospitals.

407. And that result will only be really attained by very scientific observers ?—Distinctly so.

408. We were told yesterday that some of the operations of Sir Charles Bell, by which he showed the distinction between the motor and sensory nerves of the face, were so painless that if the same thing had been done upon a human subject it would have been scarcely thought worth while to introduce chloroform; do you agree to that ?—Well, I should think so. In the first place the cutting of one nerve, the motor nerve of the face, would occasion no pain whatever; and with regard to the cutting of other nerves of the face, the sentient nerves, the pain would cease the moment they were cut across.

409. So that you would agree with the proposition which I quoted, that with regard to some of these experiments, even upon the nerves, the pain was scarcely worth mentioning ?—Yes. Moreover, they could not have been well performed under chloroform, because you would not then have had such clear evidence as to sensation.

410. Professor Syme, whom you have just quoted, was very careful, was not he, always in the infliction of pain ?—Yes; he was not much of a vivisector, indeed he was very little of a vivisector; he did not make many experiments upon animals, but he made some, and very judiciously.

411. And always did it with every regard to the sufferings of the animals that were the subjects of his experiments ?—Yes.

412. I think you have said that the experiments upon living animals may in the great majority of cases be rendered entirely painless ?—Decidedly.

413. Is there not another class of experiments where, though not entirely painless, a very great part of the pain may be spared to the animal by the proper use of anæsthetics ?—Certainly; the actual operation may be rendered painless to the animal, although a certain amount of pain may remain afterwards.

414. You instanced just now the experiment upon the arteries, and the subsequent recovery. We were told yesterday by a very eminent person that the pain of cutting and of tying an artery might be entirely taken away by anæsthetics, and that the subsequent pain of recovery would be comparatively very slight ?—Distinctly so. The arteries themselves are not very sensitive to pain; when an animal starts, or when a person starts, when an artery is tied, in amputation for example, it is generally from the nipping in of a little nerve with it in the ligature; but of course the preliminary cutting of the integuments, and cutting down upon the vessel is accompanied with more or less pain; it is not a very formidable operation as to pain; but that may be all obviated by the use of anæsthetics; and the subsequent recovery, as your Lordship says, is then attended with comparatively little suffering.

415. The number of experiments then where any very severe pain is necessarily inflicted upon an animal is comparatively small ?—It is so.

416. What is your opinion where the pain is necessarily not only great, but also protracted; are there any such experiments ?—Certainly there are some such experiments.

417. Ought there to be ?—There are cases in which they may be justifiable.

418. But those cases would be extremely rare ?—Not common, certainly.

419. And ought not, I presume, to be performed by any but some scientific and experienced person ?—Clearly; I think that all experiments ought to be performed by such persons.

420. (*Mr. Erichsen.*) Would you mention one such experiment as an illustration ?—I might mention the experiment of connecting the gall bladder with an opening in the side of an animal, and cutting off the passage of the bile into the intestines, in order to ascertain the effect of carrying the bile entirely out of the body; that is a protracted experiment and must be severe. Another very severe class of experiments, of which I think the repetition is very questionable, is experiments on starving animals to death. M. Chossat, of Paris, a great many years ago, nearly 40 years I suppose, made a number of experiments on all classes of animals, in which he starved them to death, and in some cases it took many days before the end came, and during that time of course they must have been subjected to great suffering.

421. (*Lord Winmarleigh.*) How long would those experiments of which you speak on the gall bladder last in the average ?—They would be carried on for weeks perhaps.

422. On the same animal ?—On the same animal.

423. (*Chairman.*) All the pain I understand of the mere operation would be removed by chloroform ?—Yes.

424. The pain that you speak of as so severe is the pain of the process by which the natural course of the bile is interrupted, and it is carried out of the body ?—I must correct myself there; I cannot speak very positively (because I never saw the experiment), as to the amount of actual pain that the animal endures; but it is a severe experiment, and injures the condition of the animal. In several cases they have died from emaciation after such an experiment.

425. I think you hesitate to say that experiments of this protracted kind are justifiable at all ?—I think they are justifiable, with the reserve that they must be performed with a very clear purpose, and by a very competent person.

426. (*Lord Winmarleigh.*) What is the benefit derived to the human race from that operation on the gall bladder ?—It is with a view of ascertaining what office the bile performs in the animal economy.

Mr. W. Sharpey, M.D., LL.D., F.R.S.

6 July 1875.

427. Then it is the same in the human body is it, as in the animal?—Yes.

428. (*Chairman.*) Then the performance of any such experiments as you have last spoken of, though you consider them in some exceptional cases justifiable, is to be condemned unless with those extreme reservations to which you have last referred?—Yes; with the reservation that it should be performed by a thoroughly competent experimenter.

429. If any ordinary person, say a veterinary surgeon in a country town, were to occupy himself with painful experiments, you would consider that very reprehensible?—Yes; unless he was such an experimenter as Professor Hering, of Tübingen, who made that experiment upon the rapidity of the circulation of the blood. There are men in the veterinary profession I dare say, who might be competent to conduct experiments, and in some cases painful experiments. There is a most eminent veterinarian who has conducted experiments both painful and not painful, of an important kind, on horses, M. Chauveau, of Lyons.

430. Nothing was farther from our intention than to imply the smallest reflection upon any portion of the profession, but I presume that the training, in this country at least, which qualifies people to answer the description of the exceptional persons to whom you have referred, as fit to be trusted with these painful experiments, does not apply ordinarily to veterinary practitioners in the country?—Not ordinarily, certainly.

431. Then what I want to deduce from the inquiry is this, that although in your opinion such experiments may sometimes be necessary and may be justifiable, they must be in very limited hands indeed, and that any general power of performing such experiments is a power which is very worthy of being controlled?—That, of course, leads to the question of control. I think if the Commission inquire, they will find that such experiments as we are now speaking of are very rarely performed except by professors of physiology, and others that are competent; that there is no such thing in this country as the prevalence of the indiscriminate practice of vivisection.

432. Is it your opinion that in this country the greatest possible precautions are always taken to prevent the infliction of unnecessary pain?—I do not say so; but I think it is a matter of fact that few engage in such experiments. Few are disposed or inclined to do so. I speak of it as a matter of fact.

433. Do you believe that as a matter of fact, where painful experiments are performed on animals, the utmost use of anæsthetics is always made by the persons who perform the experiments, whoever they are?—I cannot tell. In the physiological schools they employ anæsthetics; but as for the indiscriminate performance of severe operations in various parts of the country I have no evidence of it whatever, and I never understood that there was any reason to believe that such a practice prevailed in this country, and I do not think it does.

434. If such a practice should be shown to prevail it would be an evil which ought to be dealt with?—If it did prevail, certainly. If the evil existed it would be very well to provide a remedy; but I do not believe that the evil does exist.

435. We were told the other day that the worari poison is used as an anæsthetic; do you believe it is an anæsthetic?—It is a very doubtful question to physiologists. I do not think that the urari poison abolishes consciousness. It certainly interferes with the operation of the nerves of the muscles, operating on their extremities, and cutting off the power of the nerves over the muscles, although the will might remain. With regard to the sensory nerves, we are not so well informed; but I think it is not unlikely that the extremities of the sentient nerves may also be affected so as to interrupt the communication of impressions, painful or otherwise, to these nerves. But I think that is a matter which requires further investigation, and it is a question by the way for experiment.

436. But what sort of experiments can you apply which will test the difference between stopping the motor nerves and stopping the sensory nerves; the animal cannot speak to tell you whether it feels pain or not?—It is not easy. The paralysis of movement is no proof of the abolition of will; because if you cut a nerve going to a limb you still may have the will to move it; but in consequence of the continuity of the nerve being interrupted you have no power over the muscles. Now it is the same thing with sensation; but we cannot tell so clearly that the urari poison interrupts the transmission of sensorial impressions. There seems some reason to believe that it is so. A part of the body of an animal, say of a frog, may be protected from the influence of the poison which operates generally, thus a particular limb, by tying the vessels of it, is saved from the effects of the poison, and the rest of the body is affected by it; now it might be shown, and it seems to be the case (but I have not made that experiment myself), that while a certain amount of irritation applied to the part that is protected from the influence of the urari poison is followed by the evidence of pain, the same infliction upon a part of the skin, we will say, which has been affected by the urari poison is not followed by the same indication of pain, so that it is not at all clear that the urari poison does not actually prevent the sensation of pain.

437. Then if experiments *primâ facie* painful are performed upon animals with no other security against pain than that of this particular poison we have no scientific security at all that the end is really attained?—No, we have no security that the sensation of pain is abolished.

438. It is a mere chance?—It is a mere question of probability.

439. Is it even a probability?—Well, I will not undertake to say, because it is a physiological question that really has yet to be satisfactorily determined.

440. (*Mr. Hutton.*) You are aware that Claude Bernard gives a very strong opinion the other way; he says that the patient suffers just as much as ever?—Unquestionably Bernard's authority must be taken as of much weight for that.

441. (*Chairman.*) That being so, is it legitimate to hold out to the public the notion that experiments of this kind are performed under the worari poison are performed under an anæsthetic?—I should explain to your Lordship that I never held the opinion that urari took the place of an anæsthetic.

442. I never supposed that you did. I had an object in putting the question, which I can explain to you if you like?—I wished simply that what I said might not appear as said in support of the notion that urari was a sufficient anæsthetic. I was merely dealing with a nice question in physiology.

443. If the public have any rights at all in this matter to have their feelings respected, those rights are not regarded when the experiments performed under the worari poison are held out as experiments performed under an anæsthetic?—No, I think not. I think that that is not a sufficient answer to the public.

444. You have mentioned the name of Mr. Magendie; were you ever yourself a witness of any of Mr. Magendie's experiments?—I have been. I may mention to the Commission that when I was a very young man studying in Paris, I went to the first of a series of lectures which Magendie gave upon experimental physiology, and I was so utterly repelled by what I witnessed that I never went back again. My objection to those experiments was twofold. In the first place they were painful (in those days there were no anæsthetics), and sometimes they were very severe, and then they were without any sufficient object. As an example, I may tell the Commission that Magendie made incisions into the skin of rabbits and on other creatures to show that the skin is sensitive. Now surely all the world knows that

Mr.
W. Sharpey,
M.D., LL.D.,
F.R.S.

6 July 1875.

the skin is sensitive; no experiment, painful or without pain, is wanted to prove that. Then several of the rest of the experiments which he made were of a similar character, and he put the animals to death finally in a very painful way. The consequence was that I never went back to that course of demonstrations.

445. Now may I not infer that, in this country at least, and I hope in other countries also, the leading medical men and the leading scientific men may be relied upon as friends of humanity as much as eminent men in other branches of knowledge?—Clearly so. If you even take the case of those scientific men who have engaged in vivisectional experiments you will find that they do so with great reserve, and with a desire to set an example to others in that respect, and to avoid experiments that are severe unless when they are absolutely necessary for a scientific object, and in fact to discourage as far as lies in them the practice of painful vivisection.

446. This principle being, that no experiment should be resorted to except where its necessity for some useful purpose can be proved?—The question is, what is a useful purpose.

447. But assuming that the useful purpose cannot be shown, then they would desire that the experiment should not be performed?—I think decidedly so.

448. If performed where anæsthetics can be made use of entirely to annihilate pain, they would agree that anæsthetics ought to be made use of?—Most certainly.

449. And not anæsthetics such as that we have just spoken of, but anæsthetics the effect of which is perfectly well known?—Yes.

450. If experiments are partly painful, and the chief pain can be destroyed by anæsthetics, they would think it right that anæsthetics should be so used?—Certainly.

451. And if there are any painful experiments that can be mainly prevented by anæsthetics they would at least be of opinion that those should be minimised and that every merciful provision should be made?—Unquestionably. If you would allow me to say so, I think further that where anæsthetics are used it is simply a question of the sacrifice of an animal, the sacrifice of life. If the experiment involves subsequent pain after the termination of it I think the animal should be destroyed, and I think that under these conditions there need be no restriction imposed on experiments performed under anæsthetics, or in fact on experiments in which the animal is rendered insensible in any appropriate way. For instance, you render a frog insensible by destroying the brain rather than by using anæsthetics, you can render it thoroughly insensible in that way; and I think that so long as the animals are in a state of insensibility there ought to be no interference with the free use of animals for a scientific purpose.

452. But you admit clearly and without hesitation that the infliction of pain is an evil which ought to be minimised?—Certainly.

453. And you think that the Crown and Parliament might rely upon the support of the most eminent men in the kingdom if they limited these experiments with hat object?—I do not dissent from that opinion, but I have this qualification to put to it: I do not think that there are more than perhaps a dozen experimenters in this country who practice vivisection, and that not to any great extent. It is not practised by students. I have heard it asserted that it is practised by students. I can only speak of the school which I have been so long connected with at University College, and I know that there it is not practised by students. The exhibition of experiments might take place to the whole of a class of students in the lecturing theatre, or to a limited number of students in the laboratory; but in these cases the experiments are almost all performed under anæsthetics, and those which are performed before an audience of students in the lecturing theatre are very rare. I think a student ought to be admitted to witness experiments. I think the purpose of teaching a science is not simply to teach it as it is, but to enable those who engage in it to take advantage of opportunities that may occur of advancing the science, and if a student has never seen an experiment performed, and does not know the mode of doing it, he cannot take advantage of these opportunities; and he is more likely to inflict pain and do harm in his attempts to make physiological experiments. I should say, therefore, that so long as the experiments are made under anæsthetics there is no need for any restriction. And as to the question of the purpose of them the Legislature will probably find it difficult to define what are experiments "for the purpose of discovery." I see in a draft of one of the Bills which have been brought before Parliament the legitimate purpose is defined as being for the sake of a new discovery, and for no other. Now I doubt if any enactment in such terms as those proposed would be operative, because it is perfectly well known that in the history of science there has been no more fruitful cause of dispute than the question of what is a new discovery, and what is an original observation; and if the case ever came into a court, I have no doubt that you would get a number of eminent persons on one side, and an equal number on the other, who would maintain different opinions upon that, and give different evidence, although both sides would be perfectly honest in their expression of opinion; and therefore I believe that it would be impossible to get a conviction for the infringement of such an enactment. I think it is far better, if there is to be anything of the kind, that the restriction should simply be that it is "for a scientific purpose," and that you should trust in fact to the influence of public sentiment, and the example of the leading men in physiological science to correct any excesses that might be committed. I believe that in this country such evils generally become corrected in that way in course of time.

454. But in the meantime a great deal of extremely objectionable cruelty might take place?—It might take place; but I do not know that it does. I have never yet heard any evidence of it.

455 (*Lord Winmarleigh.*) How would you account for the great excitement that there is at the present moment in the public mind with regard to vivisection; do you think it is altogether unfounded?—I suppose it may perhaps be from what people hear of what goes on on the continent. It is one of those excitements in the public mind, and among a certain class of people particularly, that from time to time occur.

456. May I ask you what means you have of judging whether there is or is not a large practice of vivisection going on throughout the country?—My evidence is simply negative, that I have never seen any evidence or heard any evidence of it; and I believe if the Commission would make inquiry they would find that there is no ground for the belief. In fact I think there are a certain number of people in the country who are hunting a mere will-o'-the-wisp, and drawing sober people after them.

457. Could you give the Commission any idea of the chief places where vivisection is pursued at the present time?—I should say that in some of the schools there is vivisection going on; for instance in University College, but not by the students, and, as a rule, when of a nature to cause serious pain, the experiments are performed on animals rendered insensible—in all but exceptional cases, and these must be very few. Then I should say at Guy's Hospital experiments are carried on; and at Barthlomew's Hospital, chiefly experiments on the action of remedies; which, by the way, is a very justifiable kind of experiment to make, and very useful in medicine, to ascertain the power of medicines over the animal economy; also at King's College, and by Dr. Richardson at his private residence in London, and Professor A. Gamgee at Owen's College, Manchester. And then in Edinburgh, Professor Rutherford and Dr. McKendrick carry on experiments; and again

Mr. W. Sharpey, M.D., LL.D., F.R.S.

6 July 1875.

Professor Foster, of Cambridge, is very much employed in experiments on living animals, in fact many of his are vivisection experiments; but I know that he is equally careful in reference to the use of anæsthetics.

458. There is an impression, at least I have reason to know that there is an impression, in certain quarters that these experiments are carried on independently by men of eminence in different parts of the country for scientfic purposes, but without any control whatever, and merely to satisfy themselves?—I should explain that independent experimental inquiries are not numerous, and their nature and results are made known through scientific publications. I believe that it is an opinion without sufficient foundation.

459. If such were the case you think the medical profession generally would be able to trace it?—I think so.

460. They would be acquainted with you think? it—Yes; of course it would be a strong thing for me to say that it does not occur; all I say is that I do not know of any evidence of its prevalence.

461. Have you any knowledge of the mode in which it is practised at these other schools besides the London University?—No, I am not aware of that; I presume at any rate that they use anæsthetics wherever they are applicable.

462. (*Chairman.*) Would you be surprised if it should be proved that the worari poison is used and is called an anæsthetic, and that animals are subjected to operations which must be very painful, unless the opinion, which appears to be the less sound opinion, is proved true, namely, that the worari poison is an anæsthetic?—I have no evidence about that; I cannot tell. I dare say that the urari poison has sometimes been considered a sufficient anæsthetic, but I do not think that it is used as a substitute for such things as ether or chloroform, or chloral, or opium injected into a vein. The chief use of employing urari is to render the animal quite still; that is the great purpose of it. What Mr. Hutton says is quite true, that it is not generally recognized as an anæsthetic, and, therefore, not used as an anæsthetic.

463. Then it is a contrivance to save to the operator the trouble which the manifestation of pain by the animal might occasion him?—It facilitates the operation at any rate.

464. (*Lord Winmarleigh.*) There is one point upon which I did not quite apprehend the difference of your answers. You stated early in your evidence that you thought a repetition of Sir Charles Bell's experiments would not be justifiable; that where the facts have been successfully ascertained the experiments could not justifiably be used in the teaching of classes?—No; because in the first place they could not be used under anæsthetics. You see anæsthetics would destroy the sensibility, and you could not use such an experiment under anæsthetics. And it is a painful experiment in two ways: in the first place, exposing the spinal cord and laying bare the roots of the nerve is a very painful operation; that part of it might be done under anæsthetics, and then the animal may recover its sensibility; but the subsequent prolongation of the experiment would be painful.

465. You have restricted your answers to experiments which cannot be made without inflicting pain, when you made the observation that you would not allow a repetition of Sir Charles Bell's proved experiments if they can only be carried out, accompanied by pain?—No; because I think the matter has been so thoroughly made out already.

466. In your subsequent answer I rather understood you to say that in the teaching of classes you did think it necessary in order to teach young medical men their profession that they should see experiments, but I now apprehend that you would limit those experiments to those which can be exercised without pain?—Clearly. I used often enough to use the dead body of an animal, for instance of a dog, for certain purposes; for instance, to show the manner of determining the pressure of the blood, by connecting it with an apparatus and sending water through the blood vessels through the arteries, and using an elastic gum bag to imitate the movement of the heart; and a great deal may be done in that way; but at other times I have had an assistant to show the experiment after the lecture to those students who desired to see it in the living animal, an experiment under anæsthetics in which the animal suffered nothing.

467. (*Sir John Karslake.*) Do you agree with a gentleman who was examined yesterday, that it is almost necessary, in order to instruct students in the action of the heart, that they should see the thing itself?—Yes; I think it is that they should see it themselves, and that may be done quite well when the animal is in an insensible state.

468. Will you let me ask you about this worari; as far as you understand, it is not used generally as an anæsthetic?—It is not with that intention.

469. May I ask you this: assuming it not to be an anæsthetic, is there any reason at all why that which is clearly an anæsthetic, like chloroform, should not be used in lieu of worari?—I could not exactly venture to express an opinion, not having in my mind all the different experiments.

470. Might I ask you this: is it your view that where worari is used it is merely to facilitate the operation, to keep the animal still while it is under the operation, and not in the least with the intention of deadening pain?—Well, I believe it is with the intention really of rendering the animal still.

471. And it is assumed that in rendering it still it still suffers the pain?—That is just the point in question.

472. At all events it is not used as an anæsthetic according to your view?—It ought not to be trusted to as an anæsthetic; that is my clear opinion.

473. Then it ought to be known according to your view that if it is used as an anæsthetic it is not proved to be sufficient for that purpose?—No.

474. Now you have spoken as to what you witnessed in days long ago in Paris, when Magendie was performing his operations. Notwithstanding what he did, would you say that they were utterly unjustifiable as far as you saw; he did throw light on a good many matters, did he not, by his operations?—Yes, but some of his experiments excited a very strong feeling of abhorrence, not in the public merely, but amongst physiologists. There was that, I was going to say famous experiment, it might rather have been called infamous experiment of his upon vomiting. I do not wish to occupy the time of the Commission in stating it at length; but substantially it was this: that he substituted a pig's bladder for the stomach of a dog which he had cut out and then filled the bladder with water, and induced vomiting by injecting an emetic into the veins; and the object of that was to show that the stomach, although it has muscular coats, was passive in vomiting, and that it was emptied merely by the pressure of the muscular walls of the abdomen and diaphragm; and the experiment, besides its atrocity in point of severity, was really purposeless, because it merely proved that if a bladder filled with water was compressed when the orifice of it was left free the water would come out. Surely we did not need that experiment to show such a simple result. Yet it was shown to the French Institute, and reported upon.

475. That you would rank among perfectly unjustifiable experiments?—Yes, and it has been so characterised in the writings of other physiologists.

476. Did he not perform operations which consisted in removing a portion of the brain and keeping the animal still alive?—Those were done chiefly by Flourens and others.

477. Where those experiments which led to advance in scientific knowledge?—No doubt some of these operations on the brain have; though we are yet very much in the dark as to the brain, still a certain progress was made by certain experiments of Flourens.

Mr. W. Sharpey, M.D., LL.D., F.R.S.

6 July 1875.

478. In your judgment, could that progress have been made without those experiments ?—It is not easy to say on the spur of the moment; but I think there were points made out by Flourens, and some of those that followed him, which could not have been so well shown otherwise.

479. Now you expressed an opinion that these experiments upon live animals are not largely practised in England ?—I have a very strong opinion on the subject, that they are very little practised in England.

480. Now might I ask you whether, according to your reading or information, experiments such as you have described, namely, merely to ascertain that which you say is proved, by cutting the skin of an animal, are practised in France to a large extent; I mean experiments of that kind ?—I should not think it. There have been courses of experimental physiology besides those of Magendie, but I do not think they generally turn upon matters of that sort.

481. Then you would not say that according to your information the practice prevails extensively in France, or abroad generally ?—It is not that I am avoiding answering the question; but of late years I have not been so conversant with all that goes on abroad.

482. (*Mr. Erichsen.*) The experiments that are performed in this country are chiefly performed in medical schools according to your knowledge ?—I believe so.

483. And in the medical schools in the physiological laboratories of those schools ?—Yes.

484. These physiological laboratories have been established recently in a great measure, have they not, under the direction of the examining authorities and bodies in this country, such as the College of Surgeons ?—Yes.

485. Requiring a certain knowledge of practical physiology to have been acquired by the student ?—Yes, but not requiring that he shall perform the experiments.

486. And there is a great deal in what is called practical physiology which has nothing to do with vivisection ?—Yes.

487. And a great part of the business of these physiological laboratories is occupied with matters unconnected altogether with vivisection or experiments of any kind upon live animals ?—A great part of the work in a physiological laboratory is microscropic work, examination of the tissues.

488. And in these physiological laboratories the experiments that are made are not usually made by students ?—Not by the students. There is a thing which occurs to my mind, and which I will mention lest I should be misunderstood. Very early in my career at University College there was a very able student, a Mr. James Blake, who has long since been settled in California, who made experiments while he was an advanced student upon animals chiefly to determine the operation of medicinal and other agents introduced into the blood; and these experiments have been much esteemed and valued in physiology, and also by the medical profession.

489. It was an exceptional case ?—Quite an exceptional thing. At that time there was no physiological laboratory at all.

490. Then with regard to this point of the sensibility of animals, there are one or two questions which I should like to ask you. Are there other methods of producing insensibility to pain in living animals besides the administration of anæsthetics ?—Yes; by pithing the animal, destroying the upper part of the spinal cord.

491. That was the method of Sir Benjamin Brodie, was it not ?—Yes, it was very much practised by him. In that case all the body below the medulla oblongata is rendered quite insensible.

492. And the organic life of the animal can be maintained by artificial respiration ?—Yes.

493. So that the functions and the operations of the body go on as if the animal were alive although he is absolutely insensible ?—Yes.

494. And in some of the cold blooded animals, the frog for instance, the brain can be removed and the animal will live for a long time. For how long will it live without a brain ?—It might live for days; that is to say the circulation of the blood will go on and respiration.

495. But in a complete state of insensibility ?—Yes.

496. Have you been able to form any judgment, either from your own observation or from reading, about the relative sensibility of say, first of all, the vertebrate and invertebrate animals ?—The invertebrate creature, if you except perhaps insects, do not show great signs of sensibility; but of course they are endowed with sensibility. But when you come down to the invertebrated you come to some very low organisms.

497. Between cold and warm blooded animals, say for instance the frog and the dog, is there a difference in that respect ?—I should presume that the sensibility was more acute in the warm blooded animal. But it is an interesting fact that different animals of the same species show very different degrees of sensitiveness to pain; that has been noticed by experimenters. I think particularly the late Dr. Waller, who was a great experimenter on animals, used to point out that there were great differences in dogs, that some seemed to care very little about the operation. And a remark to a similar effect is made by Vesalius. He was a great vivisector; in his great work on anatomy he has a chapter upon vivisection, and the manner in which it should be performed; and he gives the figure of an animal arranged for the purpose of vivisection. He used dogs and he used also pigs for the purpose; and he says that in some cases, especially when you are wishing to make experiments on the voice, the pig is better adapted than the dog, because after there had been incisions made and the nerves of the voice exposed, he had great difficulty in irritating the dog so as to cause it to cry or endeavour to cry. He says that it neither barks nor howls; and apparently the inference was that it seemed to suffer very little.

498. What is the date of that work ?—It was published in 1543, I think; the first edition.

499. So that we may take it that in the 16th and 17th centuries vivisection was extensively practiced ?—Yes; indeed it goes further back; to the time of Galen. Galen says he has got a great number of different kinds of tables, on which animals of different sizes may be fastened, and he tells how they are to be fastened, and so on; and he made experiments on section of the intercostal muscles, and section of the intercostal nerves, difficult experiments, and also in cutting across the spinal cord; and he says that for that purpose you may use an adult animal; but that is not so easily managed on account of the difficulty of laying open the vertebral canal. He says he prefers a young pig a few days old, because it is easy to cut across the vertebræ over its spinal cord; and he says that he finds on cutting the upper part of the spinal cord close to the head that the animal is completely paralysed, respiration ceases, and the animal dies, but that if you cut it below the neck you merely stop the movement of the ribs, that the movement of the diaphragm goes on, and respiration goes on; and he mentions particularly the knife that he uses. He says that he prefers a knife of Noric steel, which was much esteemed in Rome.

500. That was in the second century ?—It was in the second century.

501. So that at that period, and again at the period of the revival of letters, vivisection was performed ?—Yes, and I may mention further that Vesalius speaks of showing these things to his auditors, but explains that they are shown to persons well versed in anatomy; and he says that he commonly, before making the experiment, explained to the auditors the different steps of the process, and the purposes of them, in order that he might not occupy time during the experiment by giving these explanations; and he speaks of those auditors that are near the table as being able to put their hand, and feel, for instance,

Mr.
W. Sharpey,
M.D., LL.D.,
F.R.S.

6 July 1875.

the movements of the diaphragm, and those at a distance would see certain other phenomena which it was desirable for them to be acquainted with; so that he was in the habit evidently of exhibiting these experiments to a class.

502. You were speaking of the sensibility of different animals of the same species varying?—At least the manifestation of it. I cannot well tell what they feel. I do not know, for instance, what you feel; but it is the manifestations of feeling that I speak of.

503. The dogs that are used are usually curs and mongrel breeds, and are got at a very cheap price?—Yes; it is a mistake to suppose that physiologists are indifferent to those things. I remember perfectly well when I taught anatomy in Edinburgh, and made experiments on animals, particularly with poisons, there was a bitch that was brought to the establishment that had a litter of pups; and she remained so long that she became acquainted with the people, and of course she was sent away; one would not experiment upon her.

504. To come to that point, with reference to the employment of experiments in order to determine the action of poisons on the system, there are two classes of experiments with reference to drugs and poisons, one of a toxicological, the other of a therapeutic nature; as for instance the administration of calomel to animals, and we were told by an eminent physician yesterday that those experiments are somewhat untrustworthy; is that your opinion?—You mean, as I understand, what might be called therapeutic experiments. I am not prepared to say.

505. But with reference to the administration of poisons; for instance, would it be proper in your opinion to experiment upon an animal with a new substance which might be supposed to have medicinal or poisonous properties; to administer that substance in the first instance to animals rather than to try its effects on man?—I think common prudence would suggest that.

506. It is commonly done, and it is a proper course to pursue you think?—Yes.

507. Do you think also that it would be advisable that students should sometimes have an opportunity of seeing on animals the effect produced by certain poisons?—I think decidedly; such, for example, as strychnine, which is a severe poison.

508. So that they may recognize its effects if they were to happen to see them in man?—Yes.

509. Because the effects are the same in fact?—The effects are the same. It is a more striking thing if they should ever happen unhappily to see a case of a human being suffering from the effects of these poisons, particularly strychnine; but in the absence of that experience it is of moment that they should see the effects in an animal, and then one animal would suffice for a whole audience of 300 students.

510. (*Lord Winmarleigh.*) Would you make that experiment under anæsthetics?—It could not be well made under anæsthetics, it would frustrate the experiment.

511. (*Sir John Karslake.*) Death is almost instantaneous if you give strychnine, is it not?—It takes some time, but not many minutes.

512. (*Lord Winmarleigh.*) You say there is a difference between vertebrate and non-vertebrate animals in the way of manifestations of pain?—I should rather think I was venturing too far to say that, because there are great varieties among the invertebrate animals; I cannot say how much a worm for instance may suffer.

513. If you put a worm on a hook for fishing it writhes about very violently?—I do not know that the pain is to be measured by the writhing of the worm upon the hook, because that might be produced perhaps by the muscular excitement of the animal independently of any very great sensation of pain. I cannot venture to say as to that, but if you take such creatures as polypes and sea anemones, and the like, where you may cut them in pieces and every piece grows into a new animal, I do not suppose that that involves a great amount of suffering.

514. The writhing of the worm does not you think necessarily imply pain?—Not unequivocally. I am unable to say. It is rather a hazardous thing to say.

515. Have any experiments been made upon animals which led physiologists to believe that there is a difference in the degree of sensibility in different animals?—I dare say; but you find a difference in individuals of the same species. I pointed that out a moment ago.

516. But no experiments have been made which clearly prove that any animal of the creation is free from pain under these experiments?—No. Of course there are some exceedingly low organisms, very low in constitution, and very simple in their nature, in which it is extremely difficult to interpret the phenomena, and say whether they indicate sensation or not.

517. (*Mr. Erichsen.*) With regard to the practice of vivisection abroad as compared with this country, from special circumstances you may not have visited lately foreign schools, but I know that you are well acquainted with foreign literature, and in comparing the accounts of experiments on animals as published in the scientific literature of Germany, or of France, with that in this country, do you not think that vivisection is far more extensively practised in the schools abroad than here?—Far more extensively practised. The fact is that to the credit of the scientific men of Germany, it may be said that they are very zealous inquirers in science, and there are many centres of scientific activity in the different universities of Germany, and of course that gives scope for many more experiments of all kinds, physical, chemical, physiological, and so forth; so that naturally many more experiments are performed there than here.

518. It is rather Germany now that is the centre of that scientific movement than France; France in former days I take it, and Germany rather more at the present time?—Still there is a very eminent inquirer in France, Claude Bernard, who in his day has been one of the most active and one of the most successful promoters of physiology, and much of that result has been through experiments. I do not know how far he is active now.

519. Is it to investigate known truths that all this is done in Germany, or is it to advance science?—It is no doubt principally for the advancement of science.

520. Not so much for verification?—No doubt also for verification; the establishment of doctrines; because commonly you cannot establish a doctrine by one or two experiments, and so that involves sometimes repetition, under careful conditions.

521. In your opinion, if a man wished to establish a doctrine, or a point in physiology, it would be insufficient to base that upon one or two experiments; in order to avoid a repetition of unnecessary experiments afterwards it would be better that he should perform then a series of conclusive experiments?—I think so.

522. If it were possible to do so?—Yes; but of course that would not exactly be the course that things would take, because it is quite clear that some other scientific inquirer would be disposed to take up the subject, also with a view of verifying the results, and of correcting them if necessary.

523. In connection with that, might I ask whether in verifying these results new channels of discovery are not sometimes opened up in a very unexpected manner?—Yes; a man goes out in quest of one thing and finds another.

524. (*Chairman.*) Still you would not recommend the promiscuous exercise of a practice of subjecting live animals to painful experiments by uninstructed persons, in the hope that something might turn up?—Clearly not.

525. (*Mr. Hutton.*) I think from what you said that you agree with Dr. Michael Foster in this handbook, which he has dedicated to you, when he says at

Mr.
W. Sharpey,
M.D., LL.D.,
F.R.S.

6 July 1875.

page 341 that "The methods of experiment and "observation are becoming year by year more "physical in character, and the observations them-"selves fundamental in their nature and having the "widest bearings in all the higher branches of phy-"siology, may for the most part be conducted on "frogs, may be repeated any number of times without "difficulty or expense, and so serve usefully as a "means of training students in physiological study and "inquiry?"—I think that is true.

526. The physical method is increasing rapidly?—Very rapidly indeed; but that is one of the great characteristics of modern physiology, the application of physics to the phenomena of life, particularly in making exact measurements and numerical determinations.

527. You were speaking of the German schools just now, you quite approve of the extension that this experimental method is taking in Germany?—Yes.

528. And you would like to see it extended in a similar way in England, so far as required by scientific inquiry?—Yes; the application of exact measurements and determinations by physical and chemical methods to the phenomena of life. I wish you to understand that I rather demur to the inference, that because a book was dedicated to me I adopt all the conclusions in it.

529. I did not intend to suggest that; I thought you might have read the book?—I had no fear that you would misunderstand it, but it might appear so to others.

530. Have you been able to read the book?—I have read some parts of it; I have read Professor Foster's part particularly.

531. You were saying just now with regard to anæsthetics, that anæsthetics have made a very great change, and that most experiments can be made without pain. I have looked through this book very carefully, and it seems to me that by far the larger number of experiments given in it are not made with anæsthetics at all, and that especially with experiments on frogs, which Dr. Michael Foster insists upon as the typical experiments; urari is almost the sole instrument used to render them motionless for the experiment?—Well, there is little occasion for that.

532. I am told that there is an occasion for it, that the effect of chloroform and other anæsthetics on these lower animals is so serious that it destroys the animal for the purpose of the experiment?—It may. I remember making a number of experiments on frogs myself some years ago with reference to the effects of certain poisons, and I began by trying the effect of alcohol, and found that it was such that I could not use the substances in tincture, that alcohol had a most highly narcotic effect upon the frog; but in most experiments on frogs you can destroy the brain.

533. But in a very great number of these cases given in this book, the brain is not destroyed I see, and a great many of the most instructive experiments are those of comparing frogs with the brain destroyed with those with the brain not destroyed, in order to show the difference of the results?—That is in reference chiefly to what are called the controlling centres of the reflex action; that is very true. In these cases they are not urarised frogs if it was for that purpose, but there are experiments in which the brain is partially removed. On since referring to the handbook I find that of 138 experiments directed by Dr. Foster, 113 are on (generally detached) limbs of frogs, and after destruction of the brain and spinal cord; eight on the nerve roots with or without previous destruction of the brain or pithing—in the latter case the *dissection* to be made under chloroform; seven on partial removal of the brain, the necessary previous dissection under chloroform; eight on urarised frogs; one on a rabbit on recurrent sensibility (not actually performed by Dr. Foster), the dissection under chloroform; and one on the ear of a pigeon.

534. I have read an opinion expressed by a respectable physiologist that, so far from anæsthetics having been really a blessing to animals for the purpose of these experiments, they have removed the odium of the experiments and only in a very slight degree saved the animals from pain, and certainly not the lowest order of animals?—If you take the experiments on dogs and rabbits, it has made a very great difference.

535. To them, no doubt; but as to these frogs has it?—A great many experiments on frogs can be made with destruction of the brain as I have said, and it is only now and then that these others are necessary.

536. However, I should say that in the majority of these cases given in this handbook the experiments were painful as far as I could see. Now I do not fully understand whether you justify painful experiments for the purposes of demonstration or not. Let me read this to you; it is one of Dr. Michael Foster's chapters to illustrate this proposition, that "the posterior roots are the channels of the centripetal (sensory), the anterior of centrifugal (motor) impulses," to which you referred I think. "Recurrent sensi-"bility. This is never witnessed in the frog. It can "only be shown in the higher animals, the cat or dog "being best adapted for the purpose. The method "adopted is very similar to the above, the arches of "one or two vertebræ being carefully sawn through or "cut through with the bone forceps, and the exposed "roots being very carefully freed from the connective "tissue surrounding them. If the animal be strong and "have thoroughly recovered from the chloroform, and "from the operation, irritation of the peripheral stump "of the anterior root causes not only contractions in "the muscles supplied by the nerve, but also move-"ments in other parts of the body indicative of pain or "of sensations. On dividing the mixed trunk at some "little distance from the junction of the roots, the con-"tractions of the muscles supplied by the nerve cease, "but the general signs of pain or of sensation still "remain." I suppose that is a well established experiment is it not; it is not one that is now necessary?—Certainly I do not think it is necessary for exhibition at any rate.

537. It strikes me that the intention of this book, certainly the one that ordinary readers would gather from it, is that these are experiments for the purpose of teaching a class, which should be demonstrated before a class. Would you justify that or not, supposing that is the intention of the book?—All I can say is that I should not perform that experiment before a class.

538. It strikes me that the alarm which has been caused, and which you seem to treat as a mere following a will-o'-the-wisp has been to a large extent caused by the beginning of a new school of physiology in this country, in which, besides using these experiments for purposes of inquiry, they use them also for demonstration, as seems to be the case with this book. Do you not think that that is a natural effect of the very large study of our physiologists abroad, who are bringing the views adopted abroad into this country very much?—I have no doubt that young physiologists who have been studying abroad, in the schools particularly at Leipsic and elsewhere, would naturally be induced to introduce methods followed there in their teaching in this country. I have no doubt of that; but still I do not believe that it goes on indiscriminately as has been alleged; that the experiments are carried on by persons who are not in the position of teachers for instance, or scientific investigators.

539. That I have assumed; but would you justify this, even if taught by people who are scientific investigators?—Do you mean that experiment?

540. That class of experiments, experiments of that kind; to illustrate to a class truths already ascertained, but which would be better realised no doubt by the help of an experiment?—I think that where the illustration involves anything like severe suffering to the animal it should be abstained from.

541. (*Lord Winmarleigh.*) Without any exception do you think?—I think for mere exhibition it should, unless in the case that Mr. Erichsen referred to, the

Mr. W. Sharpey, M.D., LL.D., F.R.S.

6 July 1875.

case of exhibiting the phenomena produced by certain poisons.

542. (*Mr. Hutton.*) That you would justify for the sake of making the pupils apt in the study of disease?—Yes.

543. When you said that this method is purely for scientific ends, I understood you, to put it very largely, that you did not justify this simply for the purpose of opening up inquiries with a prospect of benefit to man, but for purely scientific ends. In that sense surely it is the fact, is it not, as Mr. Ray Lankester asserted not long ago, that the number of experiments of this kind which can be performed, and ought to be performed, will increase in almost geometrical progression as the science enlarges?—I cannot venture to predict how that may be, because the progress of science supersedes so many experiments.

544. But it suggests many more, does it not?—It may lead to fresh experiments, but it supersedes many. The progress of science has been through the discovery of anæsthetics the means of avoiding many painful experiments formerly necessary.

545. Of course in every experimental science every new light must suggest a vast number of new deviations of inquiry; and it is not the less so because the *modus operandi* is painful; it will be just the same here as in any other experimental science, will it not, that every new discovery will suggest a vast number of new methods of inquiry?—Of course every new discovery widens the prospect, and brings us into wider contact with the unknown.

546. Do you not think that that is rather an alarming prospect for this country, that the number of painful experiments are likely to multiply in geometrical progression as Mr. Lankester says?—"Geometrical progression" is a very strong expression. New directions may open up in which experiments are performed. New lines of inquiry, for instance, for which experiments may be needful; but then, as said before, the progress of science tends to supersede experiments previously performed. Moreover, I apprehend that all such experiments, however extensively they are performed, would be under the direction of some skilled and competent person.

547. That we are assuming; still what you look to is that the prospect of an indefinitely larger number of painful experiments will open upon us as science is pursued?—I do not see any real prospect of that indefinite number of painful experiments.

548. Now there is a class of experiments which seems to be rather a new one, the experiment on tissue, and to which the editors of this handbook seem to attach great value. Those experiments they seem to find necessary to conduct on the living animal; and surely that is a new class of experiments?—Which do you refer to?

549. Such an experiment as causing inflammation in the cornea of a frog's eye, and then removing that as a tissue for further dealings with?—A single operation of that kind on a frog's eye would probably serve two or three dozen pupils for the purpose of microscopic examination; and I do not know that it is of a very painful character. Besides, that experiment might be made by destroying the brain of the frog.

550. It does not appear to be so made?—It might be done.

551. Would not that interfere with the result in any degree?—No; I do not think it would.

552. Then you were referring to Ludwig's method of recording the pressure of the blood. Now I am told that Ludwig has an engine at work to secure artificial respiration, which is at work day and night, or at least to a very great extent; the scale of the operations is so large?—I have seen the apparatus; there is a similar one at University College. It is simply a gas engine.

553. It is for the purpose of keeping up artificial respiration in a considerable number of animals; it would not be necessary for a few?—But these animals may be perfectly well rendered insensible; and besides it is no great matter as to whether you use an engine for the purpose or whether you use the hand.

554. Of course not; but it is simply as a test of the number of experiments requiring to be made that I speak of it; you would not have an engine for a small number?—The engine is used for a variety of other purposes, for driving lathes, for cutting bones, and the like of that.

555. Still it is desirable for the purpose of keeping up artificial respiration?—I have seen it, and I know that they do put it to that use.

556. Is it not true that with regard to those experiments for recording arterial circulation chloroform interferes so much with the action of the heart that it cannot be used?—I do not think chloroform does so much as chloral. Besides opium may be used.

557. I am told that urari is used as the great agent in these experiments, simply because it does not interfere to the same extent with the arterial pressure; and if so all those experiments, which are sometimes very prolonged (in this book, for instance, there is one of that kind which it is said may be kept up for many hours), would be experiments of a very painful character?—Well, if there was no anæsthetic they would of course.

558. You were speaking of the scientific end being the true end. I am not wishing to put you into a dilemma at all; but how would you restrict it so that it should not be extended to man. I am not speaking of ordinary men who have their freedom, but say prisoners who are liable to a certain amount of suffering for their crimes. Surely if the scientific end is the great end, those experiments would be justfiable on human beings?—But it is not necessary to use human beings.

559. It would be very much more instructive, would it not, than to make them on animals?—I do not know that.

560. You would admit that there are a great many functions in the human being which are very different from those in animals?—Of course the great point about human beings is that they could tell you their feelings. But really that speculation never entered into my head; that has been done we are told.

561. I was referring to your very strong way of putting it; you said that physiology is not a reaping machine but a plough; that we must not look to the immediate end but to the great methods that it opens up to us. Now with respect to that, surely it is quite true that that method as applied to human beings would be infinitely more powerful than as applied to animals?—I do not think we have any right to apply it to human beings, unless they are willing.

562. Even if they had incurred the penalties of the law, do you think we cannot apply it to them?—No, because the penalty of the law may be death, but not the pain that would be incurred previously; and in other cases where the penalty of the law was not death there might be a danger of it.

563. Might you not submit those who had incurred minor penalties to experiments not endangering life, and those who had incurred the greater penalty to the more dangerous experiments?—I never thought of that; if I mistake not the first experiments of innoculation of the small-pox were made on criminals.

564. Is not that a precedent that might be repeated with great advantage to science?—I have not thought out that question.

565. (*Chairman.*) You are not prepared to recommend it to the Crown and Parliament?—Certainly not.

566. (*Mr. Hutton.*) But you would admit that the way in which you put it, that the scientific object is the great object, would lead to that logically?—I do not think it is very likely to lead to it actually.

567. I do not mean practically, but that it would suggest that?—It is alleged that in antiquity they did perform dissections upon living men. It is said that Herophilus, of Alexandria did, and he was denounced by Tertullian, one of the fathers of the church, as

Mr.
W. Sharpey,
M.D., LL.D.,
F.R.S.

6 July 1875.

having made vivisections on human beings. But I do not know how far that is true, but yours is a speculative question which I really am not prepared to discuss, but I think it never will come up practically at all.

568. What suggested it to me was that you were saying that worari would be a good subject of experiments. It struck me that no experiment could be made with worari except on a being who could tell you what the result was, and that suggested that you should try it upon men; I think the logic would lead you to try it on a prisoner?—The purpose of trying it on man of course would be to ascertain whether it was really an anæsthetic, in order that you might judge how far you would relieve animals from pain in operations by the use of it; I do not see any other purpose for it.

569. It would also be very useful to know if you could relieve men from pain by the use of it?—We have other and safer means.

570. This is, I understood, to affect the heart very little, is it not?—Yes; but it may stop respiration.

571. And for various purposes therefore it might be a more useful means than those now used?—It was proposed as a remedy in tetanus, but I do not know that it ever was employed; I am not sure that it has not been employed on the human subject with that view.

572. As to those experiments on starving animals to death, was there any scientific end possible in them, to produce any scientific result of any kind?—Yes, they showed, for instance, the effect of the want of food upon the functions, upon the function of the production of heat, upon the function of respiration, and upon the order in which the tissues are consumed, the immediate cause of death, and so on.

573. They were valuable experiments, were they?—Well they were experiments that might be worth making once perhaps, but they were very severe experiments.

574. Which you would not condemn?—I should condemn the repetition of them; I should not have undertaken them; that is all I can say.

575. Now those experiments that you were mentioning as valuable at the hospitals were experiments on the gall bladder?—Those experiments that I referred to were begun by Schwann, of Louvain, a very distinguished physiologist in other branches of physiology than that, and they have been repeated by others; but I do not think that long continued experiments of that character are desirable. An experiment of that kind was made in Edinburgh, for the purpose of ascertaining the effect of mercury upon the flow of bile, under Doctor Bennett, the former professor of physiology in Edinburgh; and these were long and tedious experiments no doubt, and not very easily carried out.

576. Then even for a great scientific end you would not justify any lingering painful experiment?—I think for a great scientific end I should justify it, provided you could show that it was a great scientific end, and provided you could show that the experiment would probably give a decisive result.

577. But supposing that the experiment leads to more questions, as it usually does, than it solves. I thought you had been referring to some experiments at St. Bartholomew's Hospital, by Dr. Legg, on 16 cats, which were put to a lingering death, some of them lasting three weeks, in order to determine what the function of the liver was?—It is not right to speak of experiments which one has not read in detail; but I should think it quite possible that these experiments were not advisable.

578. Then your general position is that you would be very unwilling to have any lingering painful experiments?—Yes.

579. And that you would have them restricted, even though they might possibly lead to a scientific end, if the possible result was not clearly anticipated?—I think so.

580. But do you think that young scientific men, with the zeal of science upon them, would be likely to do what was undesirable without somebody to moderate their zeal, and to be responsible to?—I think they would. I think that if anyone had asked me my opinion upon conducting some of these experiments, I should have said that it was better not to do it.

581. Precisely; but you were not asked; and the zeal of the inquirer was too much for him. Do not you think that that suggests that some restrictive legislation is requisite, that some one should be put over these persons, or some inspector should be appointed to whom they would be responsible?—Who is competent to inspect and say what is a scientific result or not? You must trust to the persons that you permit to make these experiments. You must take care beforehand that they are persons on whose judgment and discretion you can rely.

582. But you might have an extremely scientific and even a brilliant man on whose judgment and discretion in that kind of thing you could not, I take it?—Yes; but that might happen in almost any relation of life.

583. And you would not be prepared to restrain such a man?—If you come to the question of legislation about it I think that such a person might be authorised or licensed to make these experiments; and when the experiments were painful and not done under anæsthetics that he should keep a record of them, and be prepared to report what he had done, and then the authority granting the license might from their own knowledge and by consultation restrain him from prosecuting objectionable experiments.

584. I am very glad to get that admission from you; but when you said that the greatest possible use of anæsthetics was always made by the physiologists it struck me that this handbook would hardly bear you out in that?—I cannot answer for the handbook; but I should be inclined to say that, so far as I know, in the institution which I am connected with the experiments are made under anæsthetics, or where the animal is in a state of insensibility in some way or other, and I do believe it is the case at other places; and I believe, in short, that it will be found upon inquiry that there is very little of painful experiment really practised in this country.

585. Do not you think that familiarity with these experiments breeds a certain contempt of the objection altogether, the humanitarian objection; that it creates a certain kind of scorn for the "milk sops" who feel so much for the lower animals; that there is a certain business feeling in favour of not interfering too much with the methods of science, which arises out of it?—Of course interference which would trammel scientific inquiry would be an evil; in fact it would be an act of barbarism committed at the instigation of certain people in order to prevent what they conceive to be barbarity. But I do not know that the feeling to which you refer springs out of the practice of experimenting. I think that it might arise quite independently of that. If anyone has cognizance of the nature of scientific experiments on animals, although he is not given to practise them, he might disapprove of what he would consider the unreasonable zeal of some who are commonly called humanitarians for interference. I think that may very well be; but I do not think that the practice of experiments on living animals really has the effect of blunting the feelings of those who are engaged in them or hardening their nature.

586. Not generally: but in regard to the particular experiments; they regard them as a necessary evil I suppose?—I should think if you look at the experimenters of the past you can see plainly that that notion of the moral effect of experiments made on animals is not at all justified.

587. (*Chairman.*) You have told us that in your youth you declined to attend the experiments of Mr. Magendie, although you were at that time ardent in the pursuit of science?—Unquestionably.

588. And you have told us that you reprobate every needless infliction of pain upon any animal?—Yes.

Mr.
W. Sharpey,
M.D., LL.D.,
F.R.S.

6 July 1875.

589. And that you believe the eminent men with whom you are chiefly associated are of the same sentiment as yourself?—Yes.

590. That the great majority of the experiments which you consider necessary, can be performed without any suffering to the animals if anæsthetics are properly employed?—That they ought to be so in every case.

591. But that where experiments are to be tried, which must inflict more or less pain upon animals, you think it should be under some restrictions, and that you think competent persons only should be licensed by some authority; that they should keep a record of any experiments which they perform, and that the authority should have the means of withdrawing the license if any abuse can be shown to have occurred?—Yes. I approve of all that, always under this reservation: that I doubt very much if there are such abuses of vivisection in this country as require legislative interference in order to check them, and that perhaps it might be found after due deliberation that the better mode would be to trust to the influence of public opinion and the example of the leading physiologists of the time to prevent excesses.

592. But if it should be proved that there is any tendency to such abuses in this country, as you have told us exist in your own knowledge abroad, you would think it necessary that there should be a restraint to prevent any scandal of that kind?—Well, I think so. Perhaps you would allow me to ask the favour of this extract being read, it is the opinion of one of the greatest physiologists of all time, and who is the author of the grandest work on physiology perhaps that ever appeared, and who was a great vivisector, I mean Haller: "But it is not sufficient to "make the dissections of the dead bodies of animals. "It is necessary to incise them in the living state. "There is no action in the dead body; all movement "must be studied in the living animal, and the whole "of physiology turns on the motions, external and "internal, of the living body. Hence no progress "can be made in investigating the circulation of the "blood and its more recondite movements, or the "respiration, or the growth of the body and the bones, "the course of the chyle, or the motion of the intestines, "without the sacrifice of living animals. A single "experiment will sometimes refute the laborious "speculation of years. *Hæc crudelitas ad veram "physiologiam plus contulit, quam omnes fere aliæ "artes quarum conspirante opera nostra scientia "convaluit.*"

593. But that maxim of Haller's which you have just read to us is to be understood by us, subject to all the limitations which in your valuable evidence you have been so good as to lay before us?—Certainly, it merely goes to show the importance, the extreme value and indeed indispensable need of experiments on living animals for the cultivation and advance of physiology.

594. (*Mr. Erichsen.*) I was going to ask whether physiological experiments of an important character have not been made upon men, such for example as the experiments of Dr. Stark upon himself, and those of Dr. Parkes with regard to the administration of alcohol and matters connected with the weight of the body, and experiments such as I have made myself, in giving a person various medicinal agents to see how soon they appeared in the urine?—Yes.

595. The experiments with regard to anæsthetics which led to the discovery of the anæsthetic influence of chloroform by Sir James Simpson were made upon himself and his pupils or assistants and friends?—Yes.

596. And in surgical operations in hospital practice do we not practically make experiments on the living subject, that is to say, we have to perform operations there which have never been performed before; for instance, when John Hunter ligatured an artery for aneurisun he had never performed such an experiment, nor could he have done it on animals, aneurism not occuring in them?—That is so, and I may mention Spallanzani's experiments on digestion made on himself.

The witness withdrew.

Adjourned to Thursday next at 12 o'clock.

Thursday, 8th July 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
The Right Hon. W. E. FORSTER.
The Right Hon. Sir JOHN KARSLAKE.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
Mr. N. BAKER, Secretary.

Professor GEORGE M. HUMPHRY called in and examined.

Professor
G. M.
Humphry.

8 July 1875.

596. (*Chairman.*) I think you are Professor of Anatomy in the University of Cambridge?—Yes.

597. You are also surgeon to Addenbrooke's Hospital, are you not?—Yes.

598. Has your attention been drawn to the subject into which this Commission is appointed to inquire?—Yes.

599. Will you have the kindness to state your general view on the subject?—My general view is that forasmuch as a large part of the animal kingdom lives and maintains its perfection by the death of other animals, which is necessarily attended with more or less of pain, it is quite a justifiable thing for man to inflict death and a certain amount of pain on other animals when there is a reasonable prospect of his condition being benefited by it.

600. Do you qualify that by the suggestion that any such pain should always be as closely limited as the circumstances of the case will admit?—Certainly.

601. Do you consider that experiments on living animals fall within the description that you have given?—Certainly, provided it can be shown that they are likely to promote the benefit of man.

602. Can you quote any cases which would illustrate that view of the general principle—I mean cases to show that experiments such as you would advocate are of essential importance to the welfare of the human race?—I think they are of essential importance to the promotion and knowledge of physiology, forasmuch as physiology is the study of processes going on, *i.e.*, of organic functions. Now we can attain a knowledge of anatomy and the structure of the parts by examining them after death, but we cannot attain a certain knowledge of the vital relations of those parts to one another, and their bearing on one another, except while the functions are going on; that is to say, during life.

603. Now has the discovery of anæsthetics ma-

Professor G. M. Humphry.

8 July 1875.

terially affected this question?—Unquestionably by removing a great objection to such experiments. We never could have attained to the knowledge of the action of the nervous system on the heart, and still less of that which is very important, that is to say, the action of the nervous system on the blood vessels,—an acquaintance with which really lies at the basis of our knowledge of the processes of inflammation,—without experiments on living animals; indeed, we never could have thought or even dreamt of the effects of the nerves on the vessels without actually witnessing experiments instituted with reference to this on animals in the living state.

604. Has the discovery of anæsthetics made any difference in your views on this subject?—The discovery of anæsthetics has made an enormous difference, in fact it has specially facilitated the thing; it has increased the number of experiments, and it has increased the amount of knowledge derived from them. A very great number, in fact nearly all physiological experiments can be performed as well under anæsthesia as without it. So far as my knowledge goes, they almost invariably are so; and really a physiological vivisection experiment is attended with no more pain and often with less pain than the killing of animals which is daily going on for the purposes of food.

605. Are there in your opinion very few experiments in which the pain cannot be removed by the proper application of anæsthetics?—Very few, and they would be those cases in which consciousness was a necessary feature; cases in which consciousness made a great difference in the physiological experiment, and those instances are really very few.

606. I suppose you would say that they ought therefore under any point of view to be very seldom performed?—They need very seldom to be performed.

607. I suppose if any such experiments were performed by any but the most competent people, that would meet with your reprehension?—Entirely, for this reason, that they would be valueless; it requires considerable knowledge on the subject to be able to form correct views from vivisectional experiments at all, and especially from vivisectional experiments under consciousness, for they are very much more difficult.

608. Looking at the object which we may be said specially to have in view, namely, the prevention of suffering to animals, such an incompetent person in making such experiments might, besides their leading to no practical results, inflict a great amount of unnecessary suffering, might he not?—Yes, a very much greater amount of unnecessary suffering than a competent person.

609. Now do you think that eminent scientific men in this country may be expected to take a very decided view in favour of treating animals with humanity?—I think unquestionably so. Many of them are very fond of animals.

610. And that they would be likely therefore to give their support to any reasonable measures which the Crown and Parliament might think necessary for such a purpose?—No doubt. I think they have already shown their willingness to do so. I apprehend that to them inflicting pain on an animal would be quite as repugnant as to any other persons.

611. You have spoken hitherto only of physiological experiments. Have you any observations to make on pathological experiments?—I think pathological experiments are and will continue to be very important and very useful for the welfare of mankind, in giving us a better knowledge of disease and the means of treating it; indeed, I cannot help thinking that the scientific knowledge of medicine is to be based to a very considerable extent on experiments upon animals.

612. There is a great deal of pathological observation obtained from seeing patients in hospital?—Certainly, but we cannot observe pathological processes in such patients, or only to a very slight extent. Take for instance the most common of all morbid processes, namely inflammation, we only learn what it is, and how it is to be induced, and what agents will affect it, by observations on the living animal.

613. Are those observations necessarily very painful?—Not necessarily so; some of them are likely to be attended with suffering.

614. But I should suppose that you would apply to pathological experiments the same limitation that you apply to physiological experiments, namely, that in order to be of any use they must be in the hands of very superior persons?—I would say that that limitation would apply even more strongly, because the pathological processes are more difficult to observe correctly than the physiological processes.

615. Then the instituting of experiments on living animals for the purpose of watching a pathological process by an uninstructed or comparatively uninstructed person, would result in a purposeless waste of animal suffering?—Quite so, and it would be very reprehensible. I may here state perhaps, that many of those pathological experiments cannot be made under anæsthesia. I think for the welfare of mankind and the advantage of medical service it will be necessary to induce diseases in animals in order that we may learn the nature and the processes of those diseases and the means of correcting them. For instance, we never could otherwise have known that in inflammation the globules of the blood could pass through the blood vessels into the tissues and become diseased, and find their way back again, and so enter the blood. The blood globules lie within the vessels and are confined by the walls of the vessels, which are membranes. Formerly we had no idea that the blood globules could find their way through the walls of the vessels into the tissues, and that the diseased globules in the diseased subject could find their way back again into the blood vessels. That could never have been discovered except by observations of the actual facts. It is a most important fact, lying at the root probably of a vast amount of disease. By experiments on living animals and by diseases instituted in them we are, I believe, beginning to get an idea of the nature of tubercle, and I feel it to be within the bounds of hope that one day we may learn the nature and possibly the means of preventing that most awful of all maladies, namely, cancer. I think we may look forward to that, and if it is to be found, it is more likely that we shall find it through experiments on animals than in any other way.

616. Now are those pathological experiments to which you point necessarily very painful?—I do not imagine that disease in an animal is so painful as it is in a man; still it must be attended with more or less distress.

617. But the particular distress to which you are pointing now, is not the distress of the knife?—No.

618. It is the distress of the malady which has been superinduced?—Quite so. It is quite inconceivable that anyone should enter on an investigation of that kind without very serious views with regard to it, and with great forethought and definite ideas with reference to the result to be obtained or sought.

619. So far as your own personal experience has gone, I suppose you would say with some confidence that a reckless, inhuman, and indifferent way of conducting experiments, at the cost of much suffering to the lower animals, is not to be imputed to any eminent men of this country?—I am quite unaware of its existence in this country at all. My belief is that the public statements with regard to that are very greatly exaggerated. I do not believe that those whose work it is to perform investigations of this kind would be at all more thoughtless or inconsiderate about it than other persons.

620. Those with whom you have been acquainted are some of the most eminent of the scientific men of this country, are they not?—Yes. I am not aware of vivisection being performed by other than competent men.

621. If vivisection were performed by persons who were not very competent, and who were not considerate, and who did not care to mitigate the suffering inflicted on the animal to the utmost of their power, I think you have said nobody would be so much in-

Professor G. M. Humphry.

8 July 1875.

clined to condemn it as the eminent men with whose practice and experiments you have been acquainted?—I think none would be so much inclined to condemn it as those gentlemen.

622. You would agree that anything of that kind is an abuse that ought to be redressed?—Certainly. So far as I know the experimenters do not become hardened by it. I may mention for my own part that I was very fond of shooting, and one of the things which ultimately led to my giving it up altogether, was the pain consequent on it to animals, the lingering suffering of the animals after they were wounded.

623. Have you any observations to make on the educational part of the subject?—I think it is rarely necessary in the education of the student to practice vivisection.

624. I suppose it might always be done under anæsthesis, or almost always?—I should think it might always be done.

625. And therefore to do it for the purpose of instruction otherwise than under anæsthesis would be an abuse?—Yes.

626. (*Lord Winmarleigh.*) Are there no exceptions to that rule?—There may be exceptions.

627. I mean in those cases which you have just described?—Referring to physiological processes, there is this point to be considered, that it is not easy to draw the limits of what we mean by the education of a student, for the teacher would be likely to associate his better students with him in the work of investigation and observation and reflection, which constitutes after all the best part of the education of a student.

628. (*Chairman.*) I apprehend you would say that any such investigation, if carried on at all, ought to be under the strict control of a responsible professor?—Quite so.

629. And that any latitude which permitted students to have any individual share in such matters, otherwise than under the immediate control of a professor, would also be an abuse?—Quite so.

630. Then the upshot of your opinion is, I think, that some experiments on living animals are necessary for the purpose of the development of the healing art?—Yes.

631. And that anæsthesis enables most of those which are physiological—indeed nearly all of them—to be performed without consciousness in the animal?—Yes, quite so.

632. And that in pathological experiments, the vivisectional part, if there be any, will fall under the same category?—Quite so.

633. And that the distress which would be caused to the animal would be distress of the same nature as the distress which falls on a human person when subjected to that disease?—Quite so. The only object of such an experiment should be the prevention of that human suffering.

634. And that the control of any such experiments ought to be in the hands of the most competent persons, and that any practice of anything of the kind except by such persons is a reprehensible abuse?—Yes, certainly.

635. So far as your knowledge of the principal and the most eminent scientific men of the country is concerned, you think they might be expected to co-operate in any measure which might be designed for the purpose of producing such a result?—Quite so. I may add this:—Pathological experiments I think, become more and more necessary as civilization advances. Civilization is the great engenderer of disease, and unless the healing art is made to advance in proportion, there will be as the result of civilization a distinct degeneration of man, physical and moral. I think there is no doubt of that. And therefore it is necessary to take every means possible most earnestly and anxiously to understand the nature of disease and to prevent it. It is often said that those experiments ought not to be repeated. Now we all know how very difficult it is to ascertain a fact, and those experiments on living animals are associated with observations of very complicated facts; they are often very difficult observations, and therefore they have to to be repeated and confirmed many times before the fact is really established. I might mention as an illustration of the difficulty of observation of facts, that I remember the Astronomer Royal stating that in the simple observation of an eclipse, he himself and his three assistants observed quite differently, though in that case the facts were going on before their eyes. The correct observation of the facts in such a process as vivisection is much more difficult.

636. We were told the other day that the experiments of M. Majendie established the correctness of Sir Charles Bell's views about the nerves, and that to have repeated that experiment would have been an abuse. Would you differ from that opinion?—I would not like to put the fact in quite so blank a form as that, forasmuch as there have been complications even in that very experiment,—it has not been quite so simple a matter as may be supposed,—nor have the inferences drawn from it. I do not think that the so called establishment of the facts by two observers would even in that instance have been sufficient to render further experiments unnecessary. That, however, was one of the most simple cases.

637. (*Lord Winmarleigh.*) Did I understand you to say that you did not think that these practises of vivisection were going on to any great extent in this country?—I said I did not think they were going on in an improper manner in this country.

638. Do you think that the practice is carried on to any extent in other places than in the great schools of physiology?—I am not aware of it.

639. Do you think in the course of your practice that if that were the case it would naturally come to your knowledge?—I think I should have known it to some extent.

640. Can you speak to any instance in any town or large society in England in which the practice of vivisection is carried on otherwise than under the control of some great school?—No, I am not aware of any such case.

641. You said you believed that the animal creation did not suffer so acutely as the human race?—Just so.

642. On what do you found that observation?—Their nervous system is not so large, it does not bear so large a proportion to their bodies, and we have reason to think that it is not so sensitive.

643. In what way is the nervous system not so large in animals as it is in the human race?—The nerves and the brain are not nearly so large in animals, in proportion to their bodies, as they are in men.

644. Is not it possible that a very small nerve may carry the same amount of pain as a large one?—It is not probable. It is probable that where the nervous system is largest, the sensibility would be greatest.

645. Take diseases of the face; the nerves of the face are the smallest in the body, are they not?—They are very numerous.

646. Take tic-doloreux, for instance, is not that a most acute pain?—The nerves in the face bear a greater proportion to the face than the nerves in any other part of the body bear to that other part.

647. And they give about the most acute pain that we know?—Yes, most acute pain.

648. And those are the smallest nerves, are they not?—All the nerves are about the same size.

649. If you took a worm and put it on a hook, the violent contortions of the worm would indicate to a person that was ignorant the existence of pain, would it not?—But not necessarily correctly; for there may be violent contortions and no suffering whatever; that we learn from man.

650. Could you give an instance of that?—A man may be under chloroform to such an extent as to suffer no pain, but he may exhibit violent contortions. The connection of the part with the brain might be severed altogether, so that there could be no consciousness of pain, and yet strong muscular action may be excited.

651. Take a man in a healthy state, could you give an instance in which he would be subject to great

contortions without suffering pain, supposing him not to be under anæsthesia?—In epilepsy there are violent contortions.

652. And no pain?—None; and yet there is biting of the tongue, and tearing of the muscles; it is an important point to observe that contortion is by no means a certain indication of suffering.

653. (*Chairman.*) Without affecting to be competent to ask surgical questions, I will ask this. If the nerves are divided into motor nerves and sensory nerves, then where the sensory nerve has perished, or where it has been cut off, there may be no pain and yet motion may remain, I suppose?—Yes, certainly.

654. But in an ordinary state of the body, where there is no such interruption of either class of nerves, violent motion would be *primâ facie* evidence of violent sensation, would it not?—Not necessarily, but usually it would be so.

655. That would be the presumption?—Yes, usually. Might I add here that a very vast amount of our pain is in anticipation and retrospect, which is entirely absent in animals.

656. (*Lord Winmarleigh.*) You state that you do not think that there is any very great cruelty going on at the present time under physiological practice in this country. I have in my hand an extract from (I presume) a newspaper called "The Doctor," dated June 1st, 1874, and under the head "Second experiment" I find the following: "Press your finger under " a frog's mouth until the eyeball protrudes. Then " pull down his nictitating membrane with a pair of " forceps. Next, scrape off with a sharp knife the " three layers of anterior epithelium. Now let him " rest ten minutes, you may then observe his actions; " he pokes his head down between his fore legs, " jumps, or turns over, wriggles, and otherwise acts " in a strange manner. Having watched this, take " him again and push out the eyeball once more. " Again hold down the protecting membrane, and " rub a stick of solid lunar caustic all over the eye " until the aqueous humour of the anterior chamber " shows a precipitate. Now release your frog, and " his actions will be similar to those previously " watched, but more intense; in fact, he plays such " fantastic tricks as few could look upon without that " blunting of sensibility on which so many have " dilated; it is necessary for him to be left for ten " minutes, after which his head is cut off with a pair " of scissors, and so his suffering ends. The object " is to demonstrate the structure of the cornea by " staining the intercellular substance." Do you believe that that sort of experiment is carried on in this country?—I do not understand that as a physiological experiment at all, it is a meaningless experiment.

657. You do not believe that that illustrates anything in physiology?—No.

658. (*Mr. Hutton.*) Is there not the same experiment described in a well-known handbook that has just been published?—I suppose it relates to inflammation of the cornea.

659. The inflammation being produced artificially by the nitrate of silver, is not that so?—I have glanced at the handbook and I do not think this account at all indicates that it is not done under anæsthesia. The fact of the animal being under anæsthesia is usually omitted in this book, it is taken for granted.

660. (*Lord Winmarleigh.*) Is there anything in the case which I have just put to you which pre-supposes that anæsthesia was not used?—The account would rather pre-suppose that anæsthesia was not used in that instance, the word suffering is used there.

661. From your previous answers I gather that you would say that this was a most improper experiment to make under the circumstances here related?—I think that might be done under anæsthesia.

662. But if it is not so, do you think that the experiments would be recognised by the great body of medical practitioners in this country, or the great physiologists of the day, without such an application as would diminish pain to the greatest possible extent?—I should think not. I have not considered the experiment very carefully, or the bearing of it. It seems to me very extraordinary as being performed by physiologists. I apprehend the object is to ascertain the staining of the intercellular tissue.

663. Can that be made useful for the benefit of the human race?—Yes, but the style in which this is written is I think rather peculiar: "You may then " observe his actions; he pokes his head down be- " tween his fore legs, jumps, or turns over, wriggles, " and otherwise acts in a strange manner." It would seem that that was really written for the mere purpose of exciting the feelings.

664. (*Mr. Hutton.*) Perhaps that is what might be called a sensational account?—Yes, I should doubt the veracity of it.

665. (*Lord Winmarleigh.*) You having read that, do you in fact believe that is a true statement of what has occurred?—No, I do not; I doubt it. I should imagine it to be a sensational description.

666. (*Mr. Hutton.*) There would be no doubt that an experiment of that kind would give the frog considerable pain if made without anæsthesia, I suppose?—It would give it pain, but pain in a frog is not to be measured by pain in ourselves. Still I think no pain should be given when it is unnecessary.

667. (*Lord Winmarleigh.*) You implied, I think, that pathological experiments were sometimes as painful as physiological experiments; did I understand you to say that the anæsthetic practice is as applicable to pathology as it is to physiology?—I think not, because the process may have to be observed during some days.

668. (*Mr. Hutton.*) Or weeks?—Yes, or weeks.

669. (*Lord Winmarleigh.*) You do not think that the pain of pathological experiments can be alleviated in the same manner?—Not to the same extent.

670. Would you propose to make any distinction in legislative language for this difference between pathological and physiological experiments?—I would indeed.

671. What would be the nature of the distinction which you would propose to make?—Supposing there were to be any legislation to the effect that all experiments are to be made under anæsthesia, a very great exception should be made in instances in which the process is to be extended and watched.

672. Would you make any difference in legislation with regard to the practice of pathology in these respects, so as to place a strict limit on it, or on the practice of physiology?—I should have thought that the limitation that it was to be done under responsible and competent persons would be sufficient. I confess that I have far more confidence in the good feeling of those who do such things than the public may have. I think that by limitations and restrictions you, to some extent, take away responsibility and mar good feeling.

673. (*Chairman.*) You think that if the whole subject where placed on the responsibility of one of those eminent persons to whom you have previously referred, such an experiment as you have just had submitted to you (whether it was ever performed or not, is for the moment indifferent) never would be performed at all?—Certainly not.

674. (*Sir John Karslake.*) With regard to that experiment, as far as I understand it, it was merely to show that an established fact existed which had been ascertained before, is that so according to your reading of it?—It did not appear so there, I think, but I am not quite sure.

675. I think I understood you to express an opinion that experiments of this description have increased since the use of anæsthetics became known?—Certainly they have done so, and for two reasons. First, because there are a greater number of investigators in physiology; and, secondly, the fact of experiments being possible under anæsthesia renders physiologists so much less reluctant to undertake them.

676. The latter reason seems to indicate that the medical profession generally did hesitate considerably

Professor G. M. Humphry.

8 July 1875.

to inflict pain in these cases, before the use of anæsthetics was discovered?—Certainly. I cannot conceive there being any difference of opinion about that. I cannot believe that any persons of education would voluntarily inflict pain on animals in this country, without some good reason and some great ends to be attained.

677. Do you think that those great results have been attained in consequence of those researches under the use of anæsthetics?—I think very great results are being attained, and to some extent have been attained.

678. From what date or for how many years back should you consider that the use of anæsthetics has been practically known. I do not mean as to when it was first discovered, but practically used for this purpose of vivisection?—As long as it has been known to man, that is to say about 28 years. It was about the year 1845.

679. I suppose we may take it that from the year 1845, or a few years afterwards, the increase which you think has taken place in those experiments may be dated?—Yes, certainly.

680. Though you say that when a fact has been established an investigation in this way should not go on further, is it not the case that frequently a large number of experiments have to be made in order even to partially establish a particular thing?—It is very difficult to know when a fact has been established.

681. Take a case in which you perform some operation and watch the results, and then only ascertain the fact that a particular thing has occurred in 20 cases out of 22. Is not that a common thing?—Yes; that is frequently the case.

682. You do not find the results uniform, but you find a large average in favour of a particular theory?—Yes; that is the case sometimes.

683. Now as to the use of vivisection, though we have spoken of that with regard more particularly to the benefit of human beings, you would not exclude, I suppose, the use of those experiments for the purpose of saving the lives of animals?—Certainly not.

684. You think it justifiable in those cases, subject to the same reserve as in other cases?—Yes, certainly; it is part of the law of nature that animals as well as man benefit by the death as well as the pain of others.

685. (*Mr. Erichsen.*) Referring to recent progress in physiology, made largely through these experiments, and also in pathology, could you form any idea what our present position of medical science would be if all that has been attained by vivisection were blotted out of human knowledge?—Our knowledge would be in a state of comparative barbarism. Supposing civilization to go on and vivisection not to go on, our knowledge of physiology and pathology would remain in that state of comparative barbarism.

686. It would not be sufficient for the progress of medicine or medical science that physicians should trust solely to clinical observation, or to the pathological knowledge that can be derived from observation in the deadhouse?—Certainly not; that would leave us entirely ignorant of the processes.

687. The vital processes?—Yes; the morbid process, on a knowledge of which, after all, scientific medicine must be based.

688. In the deadhouse one sees the ultimate result, but in the physiological laboratory one studies the process which leads to that result?—Yes.

689. Is there a physiological laboratory at Cambridge?—There is.

690. Are you connected with it?—Not directly.

691. But you know the proceedings there, I suppose?—Yes.

692. In that physiological laboratory are there a great many proceedings carried on that have no relation whatever to vivisection?—Of course.

693. And the students pursue their studies there?—Yes.

694. And are they allowed to vivisect or perform cutting operations on living animals?—Never, except when the animals are under anæsthesia; so far as I know it is done only by the senior students who have been deputed to do it by the lecturer on physiology, and for the purpose of ascertaining some definite point.

695. But there are many students who are not exactly *in statu pupillari*?—Yes.

696. Men advanced in years, but still students?—Yes; I should say it was impossible to define the word student arbitrarily.

697. With regard to the great advantages that vivisection has conferred on physiology, pathology, and the practice of medicine, should we not consider its bearing on medico-legal investigations. Taking experiments on animals by vivisection, do you consider them justifiable with regard to such things as the determination of the action of poisons?—Yes, certainly.

698. And the exhibition of such action?—Yes; I consider that comes rather under the division of pathology; that is to say, the effect of agents on the body.

699. All medicinal agents, for instance?—Yes; that is most important. The old notion of the effect of mercury on the liver, for instance, is disproved by investigations and experiments on living animals lately carried on in Edinburgh.

700. In those experiments, of course anæsthetics cannot often be taken?—No; not in many of them.

701. Many of those experiments are not painful, I believe?—That is so; many of them are not painful.

702. You made some reference to the comparative extent of the nervous system in different animals. I will ask you whether you have formed any opinion with regard to the difference of sensibility between warm and cold blooded animals?—Warm-blooded animals are the more sensitive.

703. You would find a difference between the sensibility of a frog and a dog?—Undoubtedly.

704. Among the warm-blooded animals, do you think it fair to compare the sensibility of the lower and higher animals, or at all events do you think that there is an equality?—The sensibility of man is greater than that of the lower animals. The question of anticipation and retrospection which I have already mentioned is also a very important point.

705. We see that, do we not, in operating on infants for harelip, for instance?—Yes.

706. It is a very severe operation, is it not?—Yes; it is less important to give chloroform to infants than to adults on that ground; there is not the dread of it, and there is not the recollection.

707. In many of those cutting experiments on animals, say, for instance, such experiments as are rendered necessary for the exposure of the carotid artery, does the animal evince much suffering?—An animal fixed down and rendered unable to move evinces very little suffering. I have often wondered at it, not being able to satisfy myself to what extent they were suffering; that was in the days when I had had some experience in vivisection before chloroform was used. Indeed, I may say with regard to the case which has attracted so much attention, namely, the case of the dogs at Norwich, I was present during a part of that experiment, and I could not tell whether the animal was suffering or not.

708. That was the dog to which absinthe was administered, was it not?—Yes, it did not appear to be suffering much.

709. (*Chairman.*) When a horse is struck with a sharp whip you can usually discern whether he suffers or not, can you not?—Yes.

710. Suppose the horse's limbs were fastened down, would you still be able to discern it?—I cannot say about the whip; I have only seen experiments with the knife, and it is remarkable how still the subjects often are.

711. Would you think it a reasonable presumption

Professor G. M. Humphry.

8 July 1875.

about a horse who was struck with a whip that we should draw the inference that he suffered a great deal of pain when he was able to move, but that if the same blow was given when he was tied down and could not move we should infer that he did not suffer much pain?—I think we cannot draw that inference. The question with me was to what extent the animals suffered after the skin was divided and in the subsequent process.

712. In the human being the external skin is the great seat of sensibility, is it not?—It is usually said to be the most sensitive, but that does not quite correspond with my own observation certainly.

713. In the days when flogging was a very customary punishment, was it not believed that the agony of the sufferer was chiefly while the skin was being perforated by the lash, and not afterwards, when the lash in a very revolting manner to the spectator ploughed into the flesh?—I do not know that.

714. Should you doubt it?—I should doubt it.

715. (*Sir John Karslake.*) The sensitiveness of the skin is very different in different parts of the body, is it not?—Yes.

716. (*Mr. Hutton.*) As I believe you were present at that experiment at Norwich which has been referred to, I will ask you a question. Do you consider that that experiment was justifiable and that the scientific object of it was adequate or not?—I was merely a bystander at part of the experiment. I heard that something was going on and went into the room, but I very soon had to leave it. I merely saw an animal on the table and some one doing something to it; what they were doing I did not know at all, and I was unable to remain and ascertain.

717. But still you understood, did you not, that the scientific object of that experiment was to try the effect of injecting absinthe into the veins or arteries of the animal?—Yes, I learned that subsequently.

718. Was that an experiment which you would consider of great scientific value?—Not of great scientific value, but of some scientific value.

719. Would not the effect of absinthe in the veins be very different from the effect of absinthe taken into the stomach?—I should apprehend not very different.

720. But it might be different?—It might be different.

721. Is there any reason to suppose that because absinthe taken into the veins would produce epilepsy, absinthe taken into the stomach would do the same?—It would not necessarily follow; but many substances produce the same or a similar effect, whether introduced into the veins or into the stomach.

722. The result of such experiments would at all events be uncertain, I suppose?—I think the fact that absinthe injected into the veins produces epilepsy is a fact of some value and importance.

723. But not as leading up to the effects of absinthe taken into the stomach?—It would have a relation to that.

724. I gather the general effect of your evidence to be, that on every account the number of these experiments must increase very rapidly in proportion as civilization which causes disease, and science which tries to mitigate disease, go on?—Yes, especially the pathological experiments.

725. I think you stated that the effect of the discovery of anæsthetics had very much diminished the pain of these experiments?—Yes, and in the physiological experiments especially.

726. Would you not rather say that it had increased the number of experiments that could be made without pain, than that it had decreased the number of experiments made with pain?—It has increased very much the number of experiments that can be performed without pain.

727. Is it not very difficult to administer anæsthetics to the frog and other lower animals?—No, I think not.

728. What is your view of the poison which is called curari or woorali. I find in Watt's Dictionary of Chemistry the following,—"This is used by the "Indians of South America for poisoning their arrows. "Curari acts chiefly on the motor nerves, the functions "of which it completely arrests, while the sensorial "nerves retain their activity." Would you agree with that view?—I have not experimented with the curari myself, and therefore I do not know, but it is quite possible for a poison to suspend motor action without suspending sensory action.

729. I find in this "Handbook for the Physiological Laboratory," it is stated that curari is largely used in experimenting on frogs. If that be so, and if the account I have just read of the action of the curari is correct, these frogs would not be under anæsthesia at all, would they?—If that is the case then they would not be.

730. Dr. Michael Foster, who is a colleague of yours, states that the number of these observations must very rapidly increase, and that very many of them may be made on frogs. In fact, I imagine that the number of experiments actually conducted on frogs is very much larger than on any other class of animals; is not that so?—There is a very considerable number of experiments on frogs.

731. I was told by a great physiologist, Dr. Klein, that there is great difficulty in administering true anæsthetics to frogs, and that many of them are killed in the process. Is that your opinion?—The lower animals are comparatively easily killed under the effects of anæsthetics.

732. The lower animals more than the higher?—The lower animals more than the higher; but nevertheless they may be put under anæsthesia.

733. But still, for the purposes of many experiments, it would be so difficult that it would hardly be thought worth while to try anæsthetics; is not that so?—I cannot say.

734. Your experience has not gone much in that direction, perhaps?—No.

735. I think I understood you to express an opinion that the line between demonstrative experiments and investigative experiments was rather a shadowy line, and one which was likely to grow fainter and fainter as medical education got better?—I think that no definite line can be drawn.

736. You would probably think that a thoroughly educated medical man ought to go through a physiological laboratory?—Yes; and that he ought to see not simply the demonstrative experiments, but possibly some of the painful experiments. Except in pathology, there would be very few painful experiments, which would be necessary for that purpose.

737. That is always supposing that the lower animals can have complete anæsthesia?—Yes.

738. At all events, I understand you to say that all medical students who are to be thoroughly educated should pass through a physiological laboratory?—Yes, certainly they should have a knowledge of the means by which certain information is acquired.

739. So that the distinction between demonstrative experiments and investigative experiments is not a very real distinction?—I think not.

740. Do you agree with Mr. Ray Lankester that the number of these experiments must increase very rapidly if the progress of science is to be kept up?—I think so; the pathological experiments especially.

741. And the pathological experiments are necessarily the most painful?—They involve a certain amount of distress to the animal.

742. They involve illness to the animal, in fact?—Yes, some of them; not all.

743. With regard to inflammation, you said that the discovery that the blood globules passed through the walls of the blood vessels could never have been made without experiments on living animals. Will you kindly tell me why that could not have been discovered by the examination of human beings who had died from inflammation?—You could not possibly tell that a given corpuscle had been in a blood vessel unless you had seen it pass through or had some knowledge that it had been previously in the blood

Professor G. M. Humphry.

8 July 1875.

vessel. Now, in an animal the blood corpuscle could be stained and be seen passing through the blood vessel, or could be found outside the blood vessel.

744. That involves not only pathological experiments, but physiological experiments on animals in a state of disease?—Yes.

745. It is not simply pathological experiments, but physiological experiments on animals artificially subjected to illness which are necessary for the purpose?—It need not be attended with very much pain; a little fluid might be thrown into the blood to colour the blood, and the investigation would soon be terminated.

746. Will you kindly turn to the account given at page 403, in the handbook to which I have already referred, and tell me whether you think the experiment there described is an experiment which ought to be exhibited to an ordinary class of students. "Recurrent sensibility is never witnessed in the frog; "it can only be shown in the higher animals, the cat "or dog being the best adapted for the purpose. The "arches of one or two of the vertebræ are carefully "sawn through or cut through with a bone forceps"?—That would be under anæsthesia.

747. But not the other part of it, I suppose?—"And the exposed roots are very carefully freed "from the connective tissue surrounding them; if "the animal be strong and have thoroughly recovered "from the chloroform and from the operation, the "irritation of the peripheral stumps of the anterior "roots causes not only contractions in the muscles "supplied by the nerves, but also movements in other "parts of the body, indicative of pain or of sensation. "On dividing the mixed trunk at some little distance "from the junction of the roots, the contractions of "the muscles supplied by the nerve cease, but the "general signs of pain or of sensation still remain." It would very rarely be necessary either to perform or exhibit that experiment.

748. Is not that given in the book as a demonstrative experiment which it is desirable to exhibit to a class in physiology?—I do not suppose that it is meant at all that those experiments are to be repeated; it is a direct experiment on the point of sensation, and sensation of course cannot be determined while the animal is unconscious.

749. Are there not a good many other classes of experiments which are very much interfered with by the use of anæsthetics; take, for instance, the experiments in the same book on arterial pressure, does not anæsthesia interfere with the action of the heart very much?—As far as I know such experiments are always carried on under anæsthesia, and I have seen a good many of them.

750. (*Chairman.*) And in your opinion, I suppose, they ought to be carried on under anæsthesia?—So far as I know, they ought to be.

751. You have been asked about the difference of sensibility between man and animals, does not sensibility differ very much in different individuals of the same species?—I think there can be no doubt about that with regard to man; I do not know about other animals. I should say that a blood-horse would suffer more than a cart-horse; but I should have thought there was not much difference between different cart-horses.

752. (*Sir John Karslake.*) Perhaps a toy terrier would suffer more than a bulldog?—About the same, I should think; but nobody can tell.

753. (*Chairman.*) If there were a restriction imposed, such as you, I think, have referred to in the earlier portion of your evidence, no students or pupils of your own would be allowed to perform any of those experiments which have been referred to, except with your own sanction?—Certainly not.

754. It would be under your own control and direction?—Just so; that is the case now. I do not know that in Cambridge any pupil ever does perform such experiments, except under control and direction.

755. In your belief then, the actual present assent of the profession to the proposition implied has already provided such a restriction?—Yes, quite so.

756. It would, therefore, not be an additional burden imposed upon them, if it were required now?—No, not at all.

757. (*Lord Winmarleigh.*) In the school of anatomy in which you practice, is there anyone besides yourself who would be authorised to perform those experiments?—Dr. Michael Foster has the physiological laboratory rather under his charge. He is specially appointed by Trinity College the prælector on physiology.

758. There is no one else who would be authorised to practise those experiments without your authority, or Mr. Foster's authority, is that so?—I do not know that I can limit it so strictly. There is a professor of medicine, and I could quite conceive that pathological experiments might be carried on under his direction.

759. In brief, would anybody who does not hold some public office be allowed to perform those experiments?—No.

760. (*Mr. Erichsen.*) I suppose we may take it that the students at Cambridge do not practise such experiments on their own responsibility and at their own option?—Certainly.

761. Such a thing is unknown?—Yes.

762. (*Chairman.*) And would be universally condemned, if known?—It would be universally condemned. I only wish that people knew exactly what does take place. I think there would not have been so much exaggeration and mis-statement if they knew.

763. (*Mr. Forster.*) Do you think that these experiments are practised in every school of anatomy?—I think not.

764. How many schools of physiology do you think there are of different classes in England?—Of schools of practical physiology I think there are very few.

765. A dozen?—I think not; I do not know half a dozen.

766. Do you suppose that these experiments of which we have been speaking are much practised by investigators in their own houses?—I think not much. I think such investigators in this country are not numerous. I would almost say, I am *afraid* they are not numerous. There is not very much physiological work done in this country.

767. Would you think that many students of physiology, or students of medicine or surgery, would in consequence of reading that handbook, which seems to recommend those experiments, try them by themselves?—I think not.

768. Do you know of such cases?—No, I do not know of any such cases. The amount of physiological investigation done in this country is not very great. I conduct a journal of anatomy and physiology, and that is the conclusion I have come to in that way.

769. I suppose you hear from men interested in physiology, medicine, and surgery various suggestions; they write to you, I suppose, as editor?—Yes, quite so. I know those who are at work at it.

770. Do you often get accounts of such experiments sent you?—Not very often; there are a few persons who make them, but it is always with regard to some especial point.

771. Can you say, as between the two classes of experiments, physiological experiments and pathological experiments by actual vivisection, which are the most generally practised?—Pathological experiments are very rare indeed; there are only one or two persons in the country carrying them out, I think.

772. (*Sir John Karslake.*) You have said, I think, that in your opinion, where a fact has been thoroughly well established, no further experiments should be made simply for the purpose of confirmation?—No further experiment without anæsthesia; but I think it is a very difficult thing to state when a fact is really established.

773. But assuming it is established, do you think you ought not to continue to put animals to pain

Professor G. M. Humphry.

8 July 1875.

merely for the purpose of ascertaining the truth of an alleged fact?—Yes, that would be a useless experiment.

774. In your profession, are the results of those experiments generally made public soon after the results have been ascertained, I mean in the different medical journals?—Any important results are of course made public. Of course there are many experiments from which results cannot be drawn.

775. But where an important result has been obtained by putting an animal to pain, it is generally published to the profession soon after it is known, I suppose?—The investigator is generally quite anxious enough to make himself known as the discoverer.

776. He is not like a patentee who wishes to keep his discovery secret?—Certainly not.

777. (*Mr. Forster.*) Have you seen any experiments performed under the curari poison?—I cannot say positively that I have. I do not know much about it.

778. (*Mr. Hutton.*) You would, I think, put the object of these experiments just as Dr. Sharpey did. You do not limit them to cases where you see a prospect of really alleviating human suffering, but you would say that simply for the purpose of extending science such experiments were justifiable?—The extension of science is for the purpose of relieving human suffering.

779. But if you did not see that object directly in view, you could justify these experiments for the other reason?—Yes, certainly, because all science has relation to the advancement of man.

The witness withdrew.

Adjourned to Saturday next at 12 o'clock.

Saturday, 10th July 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

Mr. WILLIAM PRITCHARD, M.R.C.V.S., F.C.S., called in and examined.

Mr. W. Pritchard, M.R.C.V.S., F.C.S.

10 July 1875.

780. (*Chairman.*) You are professor of anatomy in the Royal Veterinary College?—Yes.

781. Have you the care of the greater part of the infirmary?—I have.

782. Do you perform most of the operations that are performed there?—I do.

783. The late Professor Spooner was the principal there at the time of its institution, was he not?—No, he was preceded by Mr. Sewell, and Mr. Sewell by Professor Coleman.

784. But from the time of its institution the principals have been Mr. Coleman, Mr. Sewell, Mr. Spooner, and now Professor Simonds?—Yes.

785. Are the operations of which you speak performed for the cure of the animals?—Yes, entirely.

786. You have no operations for the purpose of experiments?—None.

787. Do you think it proper that there should be such experiments?—No, I think it very improper.

788. As far as your knowledge is concerned do you believe that such experiments are performed in this country by veterinary surgeons?—I am not aware of it, and I do not think it is the practice.

789. If it should in the course of our inquiry be proved to us that such experiments are so performed, you would think it very improper?—I should.

790. And you would think that persons in your own position, and such names as you have already mentioned to us in connection with your college, would be ready to support the Crown and the Government in any reasonable measures for preventing such things?—I quite think so.

791. Can you tell us what use you have made in your practice of anæsthetics?—We are in the habit of occasionally administering chloroform in such quantity as to render the animal under operation insensible, and we occasionally have recourse to the use of local anæsthesia.

792. By "local anæsthesia" do you mean such means as you think render the animal in that part unconscious?—Yes.

793. Such as what for instance?—Ether spray is introduced; continued application of cold is sometimes had recourse to,—cold water, iced water.

794. What is the reason why you do not universally employ chloroform in painful operations?—My own reason is because my experience tells me that horses do not recover from wounds so well after the administration of it, as when operated upon without it; simply because we have to administer so large a quantity that it becomes poison to a considerable extent; it poisons the blood of the horse.

795. May we take it as a fact that there is a broad distinction between the proportionate quantity of chloroform which must be taken by the horse and that taken by the human being?—I think there cannot be a doubt about it, because it is almost impossible to destroy a horse by chloroform; I believe it has been done. I have several times had horses under it for hours together.

796. Does your experience extend to dogs?—Yes.

797. What is your opinion about the sort of questions which I have put to you when applied not to horses but to dogs?—With regard to dogs I should never think of applying chloroform at all; I should think it very unsafe to do so. The dog has an intermittent pulsation; the heart's action is intermittent.

798. (*Lord Winmarleigh.*) Invariably?—Invariably. They appear for some time not to be under the influence of it at all, and then suddenly they come under the influence of it and we find it impossible to bring them round.

799. Does any cruelty attach to the death under those circumstances?—I should say not; it is an awkward thing for the operator and for the owner.

800. (*Mr. Forster.*) With regard to cats what should you say as to the use of chloroform?—I have never administered it to cats; I do not think there would be the same risk.

801. (*Chairman.*) Supposing you had a painful operation to perform on a cat, you would use anæsthetics?—I think so.

802. (*Mr. Forster.*) Ether you would apply to a dog, would you not?—My experience would not allow me to answer.

803. (*Chairman.*) Do I rightly understand you to say that the circulation of the dog being intermittent, there is much more danger that the animal would never revive than there would be in the human being?—Quite so.

Mr. W. Pritchard, M.R.C.V.S., F.C.S.

10 July 1875.

804. Then may I take it that your opinion is this, that anæsthetics ought always to be used to animals where it is possible, but that you have found more difficulty in applying them to a horse or dog than there is in applying them to a human being ?—There is more risk in the case of the dog ; and the objection I have to it in the horse is the quantity we are obliged to give.

805. Not because of the consumption of the quantity, but because of the injury done to the horse by taking that quantity ?—Quite so.

806. (*Lord Winmarleigh.*) In the Veterinary College do you ever admit surgeons in common practice to attend your lectures, or do they ever attend them ?—Occasionally they attend ; but if they desired to come continuously, that is to say, to attend a course of lectures, then they would be expected to enter as ordinary pupils.

807. Do you ever allow them to operate experimentally ?—No, never.

808. And there is nobody but yourself that is authorised to operate upon horses and dogs ?—The principal, Professor Simonds, and the assistant professor, Mr. Axe.

809. Those are officially authorised ?—Yes ; they are officers of the College.

810. Do you ever allow the pupils to operate ?—Never.

811. However far advanced they may be ?—Quite so. They administer the medicines under superintendence, but are never allowed to perform operations.

812. You cannot speak to any results except those that you have derived from horses and dogs ?—And oxen and sheep.

813. In the case of oxen and sheep, do you administer chloroform ?—Occasionally.

814. The same quantity as to the horse ?—They do not take so large a quantity as the horse, particularly the sheep.

815. Do you ever use curari ?—It has been used, but not during the time that I have been at the college.

816. You have no experience of what the effect of it is upon an animal ?—No, I have not ; no personal experience.

817. Have you any reports in the college on experiments of that kind ?—Yes.

818. What is the tendency of those reports with regard to that poison ?—Unfavourable, so far as my memory serves me.

819. Are they to the effect that it deadens pain ?—I could not say. To the best of my recollection it produced violent muscular contraction, spasmodic contraction.

820. (*Mr. Forster.*) Supposing that there was an experiment which had to be performed upon a living animal, and that the object was to do it with as little pain as possible, and that there was no hope of saving the life of the animal, what anæsthetic would you then recommend ?—Chloroform.

821. Do you think that chloroform really destroys the consciousness of a dog ?—Yes.

822. Then the fact of the circulation being intermittent would not prevent that result. I understood you rather to say that they appeared sometimes as if it had no effect on them ?—Just so ; but when chloroform is given they suddenly, as a rule, become unconscious, and we frequently find that it is impossible to revive them.

823. And if you were obliged to try such an experiment (I understand you to say that you do not think it at all necessary), you would put a dog under chloroform ?—I think you are misunderstanding the previous answer I gave. If an experiment could be performed on an animal which would bring about such a result that other animals in large numbers would be benefited, I should advocate the performance of it.

824. I was going to ask you, do you know of any cases in your study of the treatment of animals in which experiments upon living animals have enabled you to treat them with greater success ?—Yes.

825. Will you tell us what they were ?—I divided the nerve of sensation supplying a bony tumour.

826. I am afraid I did not make myself understood. It is stated, you know, by the advocates of these experiments, that not only the lives of human beings are preserved and their pain diminished by the experiment, but also that animals are better cured by the help of it. Do you know of any cases in which your treatment of animals, or the treatment of them by other surgeons, has been made better by the results of experiments on animals ?—Yes ; in cases of shortened tendons from disease, or from the shortening of them during the life in the womb. An experiment was tried some years ago of dividing those tendons, and seeing if the gap would fill up with new material, and so bring about a recovery ; but that experiment was tried upon a case, and not upon a healthy animal. It was simply this, that the animal was useless as it was, and the operation was performed for the purpose of seeing whether he might be rendered useful.

827. (*Chairman.*) What you have now called an experiment, was the case of a diseased animal, which, coming before you, you endeavoured to cure ?—Quite so.

828. It was not a case of taking a healthy animal and treating it medically for the purpose of experiment ?—No ; I have no recollection of that being done.

829. (*Mr. Forster.*) There are experiments that are made, we are told, upon animals, which are pathological experiments, not what is called vivisection, but giving them diseases and watching the process. Have you anything of that kind done at the college ?—A little has been.

830. To what extent and in what way ?—Dr. Cobbold some years ago made some experiments upon animals with parasites, with a view of determining how the animals became possessed of them.

831. Did information of value come from those experiments ?—He considered so.

832. Have there not been some experiments to try and trace the origin of the cattle plague ?—Not that I can recollect.

833. (*Lord Winmarleigh.*) There have for glanders, have there not ?—Yes.

834. (*Mr. Forster.*) Do you know anything about the Brown's Institute ?—No, I do not.

835. You cannot speak to that at all ?—Only from hearsay.

836. (*Sir John Karslake.*) As to the case that you have mentioned in which the experiment was tried on a colt with shortened tendons, what was that experiment ?—A division of the tendons midway between the knee and the fetlock ; the tendon at the back of the leg was divided to a certain extent, and then the foot brought into its normal condition ; and the question to be decided was whether the gap which existed after the foot had got into its proper condition would be filled up with such material as would allow of the animal travelling and being of service.

836*a*. Did it succeed ?—It did.

837. I suppose in that case there was reason to anticipate before the experiment was tried that it would be successful ?—Yes. I may add to that, that in every case, unless I had some pretty good faith that what I was about to try would bring about a beneficial result, I should not do it.

838. Where you were trying to cure an animal you never would submit the animal to a painful experiment unless you hoped there would be a good result ?—Certainly not.

839. Do I rightly understand you that none of the pupils in the college perform operations themselves ?—None.

840. Not even the simplest, for instance, firing ?—No ; we should call the minor operations the giving a horse a ball or drenching it ; but we should never let them use the knife.

841. (*Mr. Forster.*) When you said that some time

Mr. W. Pritchard, M.R.C.V.S., F.C.S.

10 July 1875.

ago there had been some pathological experiments, I suppose there have been no such experiments for the sake of general information as to the use of medicine of human beings. They have all been experiments bearing upon the diseases of animals, I suppose?—Directly; but I have no doubt that the human being would indirectly benefit from them.

842. Is it, or is it not, the case that at present you make use of your college for the purpose of such experiments, giving diseases to animals?—It is occasionally done. At the present time there are experiments being carried out with a view of determining some facts in connection with typhoid fever in pigs; but such experiments are not repeated for the sake of illustrations to the class, or anything of that kind.

843. But you do give a pig such a disease?—In order to determine a point which we are doubtful upon, and as to which we cannot obtain the information from any other source.

844. (*Chairman.*) In such an experiment as you spoke of about the tendons would the pain be diminished or taken away by a local application of ether?—Yes.

845. I understand from your former answers that in your operations ether would accordingly be used?—Undoubtedly.

846. (*Mr. Forster.*) You must have studied the animal frame very attentively; have you formed any definite idea as to the comparative sensitiveness to pain of different animals, as for instance between a horse and a dog?—Well, I have performed some thousands of operations on them, and I have never yet been able to detect any difference in sensation between the skin of either one or the other, and the human subject, beyond this, that the cuticle or external covering of the skin is thicker in some animals than in others, and of course the knife has to penetrate deeper to reach the sensitive structure; but when once it has reached the sensitive structure I think it is as sensitive in the one animal as the other.

847. And you think that as regards the mere physical sensation of pain it would be equal to that in a human being?—Yes, I have never seen anything to lead me to think otherwise.

848. Have you any opinion as to what it would be in the case of frogs?—I think there would be sensation to a similar extent.

849. (*Lord Winmarleigh.*) That they would be as sensitive as horses?—Yes.

850. What is your reason for thinking so?—We find that the irritation of a parasite on the external surface produces as great an irritation in the small animals as it does in the larger ones.

851. (*Sir John Karslake.*) Have you had to perform any experiments at all for the purpose of ascertaining the effects of poisons on animals; I am talking of experiments strictly speaking,—killing animals by poison in order to ascertain the effect of the poisons upon them?—Not that I can recall to mind; I do not recollect that I ever did.

852. With regard to diseases that you have given to animals, I understand that has been the case?—That has been done in the college, not by myself.

853. Have any experiments been tried in the college upon sheep for the purpose of ascertaining what the fluke disease is?—Yes.

854. What sort of experiments?—They have been experiments for the purpose of determining the early formation of the fluke.

855. Were those experiments which rendered it necessary to kill the animal in the course of the experiments?—No, but an animal has been subsequently destroyed to see the effect of what has been done.

856. The fluke will actually kill the animal sooner or later, will it not?—Yes.

857. And have you ever allowed an animal to take the pupa for the purpose of engendering the fluke in the liver or the biliary ducts in order to ascertain how long it will take to kill the animal by means of the fluke?—The effect of the administration would be noticed before the disease had advanced to such an extent, and then the animal would be destroyed.

858. That is to say, the effect would be noticed by the dropping off of the wool and the emaciation of the animal?—The first effect is the reverse of emaciation; the animal is fattened.

859. And then soon after it has fattened very much indeed emaciation comes on very rapidly?—Yes.

860. And when you have ascertained that, you kill the animal to put it out of pain?—Yes.

861. (*Mr. Hutton.*) Have you seen anything of that parasite, the trichiniæ, which caused so much alarm and so many fatal cases in Germany?—I have not made experiments with them myself, but superintended some for Dr. Cobbold some years ago.

862. You have given them to healthy animals, a I understand you?—With a view of determining the animals they inhabited, and in what way they could be conveyed to the human subject.

863. And was it with a view to determining any possible remedy or cure?—With a view to prevention.

864. Were those experiments in the result beneficial?—Yes.

865. Did you find any prevention for the evil?—If laws were carried out to prevent it under the conditions determined by these experiments, I think they would have that effect.

866. You mean laws preventing the importations of unhealthy animals—something of that kind?—Yes.

867. But no means have been discovered of curing the diseased animal when once it has got the disease?—I am not aware of any.

868. Nothing was discovered on that subject?—Not that I am aware of.

869. What is your feeling about having a physiological laboratory for experiments of this kind in connection with your institution, the Veterinary College?—My feeling is rather adverse to that.

870. You do not think that the result would be useful enough to warrant the number of painful experiments that would have to be carried out?—No; I do not think the result would be sufficiently beneficial. And again I think it would be very difficult to control or to manage it so as to prevent useless cruelty.

871. That is to say, that once an institution of that kind was set up there would be so many scientific questions put, that needless investigations would be pursued?—That is the opinion I have.

872. Have you seen any institutions of the kind, either abroad or at home, in connection with veterinary colleges?—No; my experience when I was abroad, although I cannot say but what they behaved very courteously to me, was that I was not allowed to see anything that might have been going on of that kind; that is the impression I had.

873. Will you tell me what the operation for navicular disease is, and whether you consider it a beneficial one?—It consists of dividing the nerve of sensation supplying the foot or the feet.

874. And it is not injurious to the animal eventually, you think?—I think not, not if the case is properly selected.

875. It is sometimes said that it is giving the animal intense torture, simply to make it appear to grow better; what do you say to that?—That is a very erroneous impression. The wound in the skin is not more than half an inch in length, and the division of the nerve is instantaneous; and the leg is prepared anæsthetically.

876. I did not mean the intense torture of the operation, but the subsequent effect; is it great pain to the horse?—No.

877. Not at all?—No.

878. And has it no bad effect on the nutrition of the bone?—No.

879. You know of no experiments on healthy horses for the sake of investigating the cure of that disease?

Mr. W. Pritchard, M.R.C.V.S., F.C.S.

10 July 1875.

—No; I never recollect one at all. I am sorry to say we have too many diseased cases to need any experiments on healthy ones.

880. In fact you have quite enough experience without trying it on healthy ones?—Yes; I am afraid that the majority of horses at the present time in London are affected with navicular disease.

881. (*Mr. Forster.*) What is that?—It is an ulceration of the little bone which we call the navicular bone.

882. (*Mr. Hutton.*) You do not, as I gather, look for much good to animals from a physiological laboratory where these experiments might be performed for inducing disease; but it would be rather for the benefit of men than of animals?—I should not like to say that they would produce no beneficial effect; but I do not think that the effect would be of sufficient importance to lead me to advise that such an addendum should be made to our institution.

883. (*Mr. Forster.*) And also you find that the information is obtained in the process of trying to cure the animal which supplies the place of experiments?—To a great extent.

884. (*Mr. Hutton.*) And much more to the point, I presume?—Far more to the point.

885. (*Mr. Forster.*) You know that there are two theories with regard to curari, one that it does destroy consciousness of pain, the other that it does not, but merely prevents muscular action?—Yes.

886. Have you any opinion on the matter?—I have not.

887. In that state of doubt would you think it safe to use it as an anæsthetic?—I should not use it.

888. (*Mr. Hutton.*) Would you inject opium into the veins for dulling the pain? Do you ever do that with animals?—I think it was done sometimes in the cattle plague, but the effect produced did not guarantee our repeating it.

889. Practically you use nothing but chloroform and ether?—I myself use chloroform, ether, and local anæsthesia.

890. (*Lord Winmarleigh.*) I think you said that you were not conversant with any experiments with a view to ascertaining the nature of the cattle plague?—I was engaged for the Government myself in connection with Professor Varnell, then an officer of the college, to endeavour to find out a cure for it.

891. What experiments did you make with that object?—We administered several classes of medicines, and had recourse to outward appliances of different kinds and character.

892. You never made use of the disease itself by inoculation or anything of that kind, I suppose?—I could not say without referring to my notes; but I believe that inoculation was resorted to with a view to determine whether a milder attack would not be the result; but we did not find that it succeeded.

893. Did you find that any of your experiments succeeded with a view to stopping or alleviating the cattle plague?—No, they entirely failed.

894. Were any of those experiments which you made of a painful nature to the animal?—No, I do not think so, beyond the pain of injecting the material into the veins.

895. (*Chairman.*) The experiment was followed by whatever distress the cattle plague itself involved?—Quite so.

896. (*Mr. Forster.*) There have been experiments with inoculation for pleuro-pneumonia, have there not?—Yes.

897. (*Mr. Hutton.*) Have you had any experiments for the foot and mouth disease?—I have not personally carried them out, but I know there have been some carried out at the college.

898. You do not know with what result?—I could not speak as to the results.

899. (*Sir John Karslake.*) Were they experiments on diseased animals?—No, on healthy animals.

900. (*Lord Winmarleigh.*) Have you any belief that any future experiments that may be made on living animals may tend to the cure of the cattle plague, if it should occur again in this country?—No.

901. (*Chairman.*) Your opinion with respect to experiments on healthy animals, for the purpose of curing or relieving the sufferings of other animals, is an unfavourable one?—Yes; as to the majority of diseases there are some of which the spread may be prevented or avoided, but in the majority of cases the results are unfavourable.

902. But how can the experiment on the healthy animal prevent the spread of the disease to other animals?—By determining whether the disease is contagious or infectious.

903. That is to say, discovering whether it is contagious or infectious leads to greater care in the management of the disease?—Yes; and so prevents its spreading.

904. (*Mr. Forster.*) As regards inoculation, if you could have found that inoculation was a cure for cattle plague it might have been of immense advantage to animals?—Yes, as has been the case with small pox in sheep.

905. There it answers?—There it answers.

906. As regards pleuro-pneumonia it is still a question of doubt whether it answers or not, is it not?—Yes; the experiments have not led to any decided results at present.

907. (*Mr. Hutton.*) As regards drugs, do you not find that the effect of drugs on animals and on the human frame are exceedingly different; for instance, you can give much larger doses of aloes to dogs than to human beings, can you not?—Yes.

908. And generally would you say that the effects of experiments with drugs on animals are instructive, or not instructive, with regard to their effect on human beings?—I do not think that the use of drugs on animals can be taken as a guide to the doses or the action of the same drugs on human subjects; and therefore I do not think they are instructive, or only to a slight extent.

909. (*Lord Winmarleigh.*) At any rate they cannot be depended upon?—They cannot be depended upon.

910. (*Mr. Hutton.*) That does not apply to the severer poisons, but to drugs meant for healing?—Some things may be learned from those experiments, but they are not to be depended upon.

The witness withdrew.

Adjourned to Monday next at 12 o'clock.

Monday, 12th July 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

MR. HENRY WENTWORTH ACLAND, M.D., F.R.S., called in and examined.

Mr. H. W. Acland, M.D., F.R.S.

12 July 1875.

911. (*Chairman.*) You are Regius Professor of Medicine in the University of Oxford ?—Yes.

912. And a Fellow of the Royal Society ?—Yes.

913. And President of the Medical Council ?—Yes.

914. Has your attention been drawn to the subject which is referred to this Commission ?—Yes, it has been.

915. For a long period of time ?—I think that I first considered the matter about 33 or 34 years ago.

916. And what drew your attention to it at that time ?—I was then a medical student, and the subject came before me in the course of my anatomical and physiological studies.

917. And what impression have you formed in consequence ?—That question is so large an one that I scarcely know in what way to answer it.

918. Is it your opinion that experiments upon living animals are or are not necessary for the investigation of medical subjects ?—The first answer I should give to that would be, that human knowledge would be entirely in a different position from that which it now is if such experiments and observations had not been made.

919. Then you consider that they are necessary ?—That does not follow from that statement.

920. Then what may the Commission consider to be your view as to the necessity of them ?—I think that if it is essential thoroughly to extend human knowledge in that direction, then observations and experiments of this kind may be counted to be necessary.

921. Do you know the resolutions of the committee of the British Association ?—Yes, I have them with me here. The first of them refers to the influence of anæsthetics in the conduct of such experiments. But I would observe that by far the greater number of the experiments which have added to human knowledge in this direction, were conducted without anæsthetics. I merely wish to note that as a matter of fact, and that at the time when I first seriously considered the subject they were necessarily so done, for anæsthetics were not known. At that time there were a number of experiments and observations of the highest class, which had been conducted by Sir Benjamin Brodie, Doctor Hope, and others; those experiments related to the nervous system, to the circulation of the blood, and to the structure of the heart. They were of such a kind that I suppose their results could not have been attained in any other way. They were made (and I am anxious with your permission to make this statement) by persons not only of great intellectual power, but of tender and gentle natures; they were in themselves experiments of a revolting and grave nature—but they were done by such men. They no doubt did produce great results to medical science. There is no question about that. But it is right to add that from their nature some were made upon animals just killed, and, therefore, they were not, properly speaking, upon living animals. When I knew that the Commission desired to ask me questions on this subject, I felt that the first thing that I should have to ascertain was what exactly the Commission means by "vivisection."

922. The word vivisection is not used in our Commission; the term is "experiments on living animals"? —Then that comes exactly to a point about which, at the outset of anything that I have to say, I should desire to be one at with the Commission. There are observations made upon living animals which are absolutely harmless in every respect. I will mention at once one class which is well known to the members of the Commission,—observations upon the circulation of the blood made in transparent textures. These are a series of observations which have been made on the circulation, first in vegetables, and secondly in animals. The observations on circulation in vegetables manifestly are of course harmless, because we presume that vegetables suffer no pain; we do not perhaps certainly know that, but we presume it. The next are observations upon transparent textures of animals, of which the most notable is on the web of the frog. Now an ordinarily careful person will tie the toes of the frog with silk threads and keep them open, and so examine the circulation in the frog's foot, and this I understand is considered not cruel. Yet I have heard objections taken, and they have been taken against myself, for tying the toes of the frog in that manner for the observation of this web. That I think is an absurd objection. But now comes this, — that in order to observe these transparent membranes, some persons I believe, with entire indifference, take a living frog, open the abdomen of the frog, spread out the interior living membrane, called the peritoneum or mesentery, and there observe the course of the vessels. Now if the frog suffers pain, that is as painful, I suppose, a thing as can be done. So when we want to observe the circulation, we observe it in vegetables, we observe it in an almost painless way in an animal, and we may observe it in a painful way in an animal; and now mark the result. About the time I allude to, 30 years ago, there was a great impulse in every department of biological knowledge from the manufacture of improved microscopes. Therefore a great number of experiments and observations came to be made of such a nature as I have described, which could be performed before either painfully or not. I will not say that the painful experiments were needless, because I think there were some points that could be made out by painful experiments, that perhaps were not to be made out by others. At all events the amount of knowledge that was gained by this practical observation of the circulation in living animal structures is such that it transformed the whole of our conceptions of the animal economy, and made things, which were matters of speculation before, matters of certainty, just as certain as that the despatch box before you is on your table. I mention these simple cases as an illustration of what seems to me to be the graduated difficulty of the question before you.

923. But you said that some of these experiments were painless, that some were severe, and that nearly the same result might have been obtained from the painless experiments as from those which involved severe suffering ?—I did; but if we were to attempt to go into the whole history, either of the experiments or of the actual knowledge which has been obtained from them, and to sift out of that mass of information and of history all that was serviceable and all that was not serviceable, all that was needlessly cruel and all that was necessary torture, we should find ourselves involved in a task which would occupy me, at all events, if I were to undertake it, many months. I do not know whether I could ever complete it, for this reason, that it has been necessary in the

Mr. H. W. Acland, M.D., F.R.S.

12 July 1875.

pursuit of physiological knowledge to make experiments in order to know what would be their result; and, therefore, when a person originally took the mesentery of a frog in order to examine it, I do not necessarily say that he was cruel. What I do think cruel is this (and this it is of importance for the Commission to observe), that when a thing is once established, and when we know all about it, needlessly to repeat the experiment over and over again.

924. Without stating positively that a particular experiment is in itself so severe that it ought not to be practised at all, you are quite prepared, are you not, to say that if a severe experiment has once been satisfactorily performed it is a needless cruelty to repeat it?—I am not prepared to say that absolutely and without reserve. I have no doubt that that would be excepted to by scientific men; because an experiment which is entirely satisfactory at one period of science may afterwards turn out to have been done under conditions from which something or another was excluded which modifies it. Therefore I would not say that Sir Benjamin Brodie's experiments, or other experiments which seemed to have settled and which did settle points at one period, might not require to be repeated at a subsequent one. With that reservation I should agree to the doctrine.

925. As a general doctrine you agree that an experiment involving severe suffering ought not to be tried upon a living animal, unless it were for the purpose of establishing some new and very important doctrine?—Generally speaking, I should say certainly.

926. And did the Commission rightly collect your impression that there was not 34 years ago on the part of everybody the desire that there might have been to limit painful experiments?—I do not think that I could answer that question with certainty, because it would imply a considerable personal knowledge of the individuals; but this I will say, that I am quite convinced that the men most to be depended upon in science, first of all would never waste their time, and secondly would never perform a single painful act which would needlessly give suffering to any creature—not such persons as Brodie or Hope, and I might mention many others. I am sure they never do so.

927. Do you draw from that the inference that such experiments should, as far as possible, be limited to persons of that degree of eminence?—Well I am inclined to think so now, but I am not therefore inclined to say that 25 or 30 years ago, when the first burst of this knowledge came upon the world, students were wrong in verifying observations; at all events I do not think they were morally wrong. I saw several myself and joined in them myself, and I do not think that I was morally wrong in doing so.

928. But without committing you to that opinion, are you of opinion that a reasonable limitation of such practices might be entertained by the Crown and Parliament?—Certainly, it might be entertained. Whether I am prepared to say that observations made for purely scientific purposes should be under the control of ordinary legislation is another question. I have not made up my mind that they ought.

929. If it were to appear that persons of comparatively inferior scientific knowledge and training resorted to such experiments, would you think that that was a state of affairs which called for the intervention of Parliament?—That seems to me to be a question which the Legislature and the Government have to settle. A scientific man ought to be slow to admit that it is necessary that the law should step in to regulate his mode of study. If the law steps in and physically coerces my mode of study, I must submit to that law the same as to any other. Yet I have a great unwillingness, as a scientific man, to admit the necessity of the law interfering.

930. The question that I put to you did not refer to persons of high scientific knowledge and attainments, the question was whether, if it should come to the knowledge of the Crown and Parliament that persons who were inferior in those respects nevertheless took upon themselves to practice painful experiments, you would see any objection to an interference with that latitude on their part?—No, I should see no objection to that at all, if a case can be clearly made out; but the question would arise at once in practice, who were the persons who were to be so coerced or so looked after as a matter of police regulation. In any well-conducted medical school I do not think that it ought to happen. I am quite sure, for instance, that at Oxford it could not happen now, because my colleague, Professor Rolleston, a man of great acuteness, and of still greater benevolence, would not allow anything of the sort in his establishment. And I should say the same of many whom I could point out. It is invidious perhaps to name living persons, but I will say the same of two of the most eminent observers and physiologists living, Dr. Allen Thompson of Glasgow, and Dr. Sharpey, who has lately retired from University College in London. It is inconceivable of these persons that anything should go on within their knowledge, otherwise than what it is right for them morally and intellectually to permit. And now that the scientific sense of England is called on to decide on this matter (and I am very glad that it is), I should much doubt whether the best judges of what class of vivisections should be performed, would not be either the heads of the chief departments of science or some scientific body, or somebody nominated by them for the purpose. I am not sure about that, because I think the Commission might at once ask me if I disapproved of the Anatomy Act, and if I disapproved of the inspection of the dissecting or anatomy schools, which I do not.

931. I am sure you will forgive me for repeating the question, because it is a very delicate part of the inquiry, and I only wish to get at the bottom of your thoughts by constantly dwelling upon the points until I have done so. What you have now said is that whatever should be done at Oxford for the purpose, or at the London University or at Glasgow, under such names as you have given, should be left to the discretion of those persons; but you have not yet said whether, if it should appear that persons of no such discretion, no such attainments, and no such general competency as those persons, do practice experiments upon living animals, it would be unreasonable and improper to take measures for controlling those persons?—I meant emphatically to answer that in the affirmative. I meant distinctly to say certainly if that can be established; because persons who wantonly or carelessly, for no good to mankind, and perhaps with great injury to themselves as well as to the animals, did so, ought to be dealt with as you deal with the other brutal part of the population. My reason for directing my answer to scientific bodies and the managers of schools is because, upon the whole, these experiments which, when conducted to any good purpose, are matters of extreme delicacy and difficulty, are only done in scientific establishments.

932. Now, since the period to which you have adverted, namely 34 years ago, anæsthetics have been discovered?—Yes.

933. Have they very materially changed the bearings of this question?—They have changed them so far as this, that you can perform most experiments without causing pain to the animal. Of course that is a great point gained; but I am not at all prepared to say that I think that even experiments causing painless death needlessly ought to be performed. I know there are two opinions about that; I know some persons think that it is a matter of entire indifference to take away the life of an animal. I do not think so; I should act in a way which would do great injury to my conscience if I were needlessly to put to death the meanest animal; I could not do it. And, therefore, I cannot say that because I can put an animal to death without pain, therefore I may unnecessarily destroy an animal, in order to show a thing which I can show just as well upon a diagram.

Mr. H. W. Acland, M.D., F.R.S.

12 July 1875.

934. But some experiments which would fall into the category of the necessary experiments, as you have laid it down, can be performed now under anæsthetics, can they not ?—Yes.

935. A great number of such experiments ?—Yes.

936. Therefore, whereas it was necessary 34 years ago in your opinion to inflict pain, it is no longer necessary to do so in those cases ?—I imagine that to be the case.

937. Are there not a great number of other experiments of which at least the greater part of the pain may be removed by anæsthetics ?—Surely ; probably there are very few that cannot be performed under anæsthetics.

938. Then I think we may collect from your evidence that it is the bounden duty of anybody performing such operations to minimise the pain as far as possible ?—I presume that that is generally if not universally so done in this country.

939. At any rate you think it ought to be done ?—Certainly.

940. And if there were any cases established in which that was not the practice, it would appear to you to be a circumstance calling for the consideration of the authorities ?— For their consideration. Observe again, I do not say for legislation, but I say for consideration. I believe that any such persons would meet their own punishment. I will undertake to say that such cases could very rarely happen, for instance, in London ; that a thing which would so shock the sense of the medical profession as operations of this kind performed habitually without chloroform, to the best of my belief (I may be misinformed), would simply produce a great disturbance ; and it would so shock any assembly in which it was done, that I do not imagine that there is an operating theatre or dissecting room where such a thing would be tolerated as performing any cardinal operation causing suffering to any extent without anæsthetics ; and if it be so I should be truly sorry to hear it, and it is a new fact to me.

941. I am not suggesting that such is the fact ?—It is so abroad. I have every reason for believing that it is often done abroad, with what I should call an unscientific carelessness, which I believe would be so hurtful to the moral sense of England that it would not be endured. But with regard to these facts, I ought to add that I have been so occupied in other departments since I was reader in anatomy at Oxford, that I have not visited the foreign physiological laboratories of late ; and, therefore, testimony on this point should be got from persons such as Dr. Rolleston and Dr. Humphry, and others who are still teachers of anatomy and physiology.

942. But it is your confident opinion that the public feeling in England secures the English community against the infliction of purposeless and uncalled for suffering upon living animals ?—In the medical profession, as far as I know, that is the case.

943. (*Lord Winmarleigh.*) That observation does not apply to the public generally ?—I cannot answer for them.

944. You cannot answer for the public generally. Your observation applies to the medical profession ?—I say that, because I imagine that these inquiries are for the most part confined to the medical profession, or persons allied to the medical profession. There are, however, biologists now in the country who are not medical men, and they are increasing in number ; I think that the Commission ought to be aware that the number of persons in this and other countries who are becoming biologists, without being medical men, is very much increasing. Modern civilization seems to be set upon acquiring, almost universally, what is called biological knowledge ; and one of the consequences of that is, that whereas medical men are constantly engaged in the study of anatomy and physiology for a humane purpose,—that is for the purpose of doing immediate good to mankind,—there are a number of persons now who are engaged in the pursuit of these subjects for the purpose of acquiring abstract knowledge. That is quite a different thing. I am not at all sure that the mere acquisition of knowledge is not a thing having some dangerous and mischievous tendencies in it. I know that would be thought by many persons a very *arriérée* and foolish opinion. Nevertheless I am not at all prepared to say that the mere desire to attain so much more knowledge is a good condition of mind for a man ; at all events it was not the way in which all this mass of physiological and biological learning was added to the world, because it was added to the world by men who were obtaining it for the sake of doing good with it—doing good I mean to their fellow creatures by relieving suffering ; that was a chief incentive to biological studies. But now it has become a profession to discover ; and I have often met persons who think that a man who is engaged in original research for the sake of adding to knowledge is therefore a far superior being to a practising physician who is simply trying to do good with his knowledge ; that he is a superior being, because he is devoted to pure research. Now that introduces a new element into the question, and I believe it will be found that a great part—not the whole, observe—of this difficulty has arisen because there has come to be a pursuit of knowledge in this direction, just as you pursue knowledge of metals with the ordinary apparatus of a chemical laboratory. So many persons have got to deal with these wonderful and beautiful organisms just as they deal with physical bodies that have no feeling and no consciousness. The multiplicity of these investigations, I have no doubt, has in a great measure arisen in that way.

945. (*Chairman.*) This desire for knowledge on this subject is spreading all over Europe, including this country ?—Yes ; certainly.

946. And although, so far as you know, there has not yet grown up any indifference to animal suffering in this country, yet it is your opinion that a great deal is done on the continent in the way of experiment, which in your opinion would be very shocking to the sentiment of the people of this country if it were done here ?—Yes, according to what I am informed on what seems to be credible authority. If things were done in London which are, as I am informed, habitually done in some one or more laboratories on the continent (I do not specify them, because I have not visited them), I believe they would not be tolerated. Whether that be true or not the Commission can easily ascertain from other witnesses.

947. I asked you a little while ago whether you were acquainted with the resolutions of the Committee of the British Association. Do you agree with them ? —Upon the whole. I think the first, which says that " No experiment which can be performed under the " influence of an anæsthetic ought to be done with- " out it " is so obvious that I am almost ashamed of having to assent to it. Of course it ought. Then the second is, that " No painful experiment is justifiable " for the mere purpose of illustrating a law or fact " already demonstrated, in other words, experimen- " tation without the employment of anæsthetics is " not a fitting subject for teaching purposes." I assent to that. In fact I go further than that, because I do not think that experiments ought to be performed on living animals which either give them suffering or cause their death without necessity. I should feel it, as I have already said before in other words, in myself an immoral act as a teacher, remembering that I lectured on anatomy for 14 years,—I should think I was guilty of an immoral and unjustifiable act if I ever showed upon a living animal, so as to cause its death or suffering, a thing which could be shown by diagrams or dissection. I have made hundreds of dissections for the University of Oxford, which are preserved now, in order that these dissections may not have to be repeated. They are preserved for study, because these things have to be seen. They took a great deal of trouble and expense to prepare. A number of persons, such as John Hunter and Professor Owen, have spent a vast amount of labour in

Mr. H. W Acland, M.D., F.R.S.

12 July 1875.

making these dissections to show to other learners. It is not necessary in order to show the heart of a fish or a rabbit or any creature to destroy the creature to show it, because I have already got them put up in the museum. I should think it wantonness to kill an animal in order to show a thing when it is already shown in an animal which I have dissected and put up in the museum. The third resolution contains these words, " For this reason no painful experiment " ought to be performed by an unskilled person, with " insufficient instruments and assistants,"—of course not,—" or in places not suitable to the purpose,"—of course not. These resolutions seem to be things about which there cannot be two opinions. The only doubt is whether they are to be enforced by law; about the propriety of them there can be no question.

948. And whether they should be enforced by law would depend in your opinion, I think I have collected, upon whether it was established that a necessity for such interference existed in this country ?—Yes, I think so. If the Commission collects evidence which shows that the scientific men of England are careless and wanton, then I say that we deserve the humiliation of being looked after by the police; but I think it will not turn out so.

949. But you have already said, I think, that, without in the least degree supposing that any eminent scientific people are capable of anything of the sort, if it should turn out in evidence that any other persons practise anything of the sort, then it would be right that there should be some legal repression to prevent a recurrence of that evil ?—I have no objection to say that, because, as I said before, it will, I suppose, be found very rarely to occur, difficult to establish, except in the case of wanton and careless students, who I should have supposed would, under the existing law, be punishable under the Cruelty to Animals Act or some other Act; I mean in cases where they are not pursuing the experiment for scientific purposes; in such a case it is an act of wantonness, and if there are any schools where such things could go on, the schools themselves are not fit to exist as schools.

950. Nothing is further from my intention than to suggest to you that there is evidence before us at the present time that anything of that sort does exist; I merely put the question to you hypothetically, the hypothesis being so far sustained that, in your opinion, there are many things done on the continent which would fall within that category ?—Yes.

951. Has this subject been brought before the General Medical Council ?—No, it has not; and I am glad that you have asked me that question, because it enables me to say that it would have been brought before the Medical Council this year, at the session which has lately closed, had it not been that the Government had appointed your Lordship's Commission. We were going to discuss the question of the extent to which what is called practical physiology, which means in great measure this subject, was requisite for students; but my colleagues who were going to bring the matter forward felt that it would be more seemly if we delayed until after your Lordship's Commission had reported, and so the subject was for the time dropped; otherwise it would have been brought forward.

952. We have hitherto spoken chiefly of physiological and biological experiments. Are there not many experiments which are called pathological ?—Yes. These investigations may very properly be divided into four classes,—physiological, pathological, surgical, and toxicological; that is, into the actual structure and mode of action of living beings, their diseases, the way of treating them in surgery, and the way of examining those agents which are injurious to life and productive of disease. Now, with regard to the class of which your Lordship asked me, the pathological, there are a number of experiments which are not properly called vivisection, I suppose,—experiments on animals,—of which, one of the most notable or characteristic is the production of consumption. Experimentalists have endeavoured to ascertain the condition under which the disease called consumption speaking broadly, or tuberculosis as they technically call it, may be produced in animals. Now at first sight it seems to be a very useless operation to try and cause consumption in a rabbit or guinea pig, or any other animal. But supposing that by ascertaining how it is produced you can ascertain how to hinder its being produced, what then ? A more curious instance than that has occurred, because that happened to be not a very difficult thing. Brown-Séquard, one of the greatest experimentalist in this department of knowledge, has ascertained how to give epilepsy to guinea pigs; and that is a very singular thing; but further than that, he discovered how to make it hereditary in them. Now, supposing that having found out the way in which epilepsy was transmitted to the descendants of animals, he was to find out the way to hinder its being transmitted to human beings, what a result that would be! The public, who are not familiar with the complicated mode of investigation and reasoning which goes on in Medicine, can hardly appreciate the difficulties and magnitude of the questions involved. I think that the examples of epilepsy and of consumption which I have mentioned are an illustration of that. Even for us, who spend our whole lives in it, it is very difficult to follow the intricacy of some of these inquiries. The public are very much interested in one, viz., the origin of man, the Darwinian hypothesis. The transmission of national characteristics includes the origin and transmission of diseases; and so the medical inquirer gets entangled in almost every department of human knowledge. I do not think that those who are not specially versed in the subject are right, unless they are very lenient, in judging of the characters and works of great investigators, such as Brown-Séquard.

953. The inference may be drawn, may it not, that such investigations as those require persons of the highest competence ?—The very highest. It is a very rare quality, that of being fit to do these things; it is a very rare thing even for a medical man, or for a professed physiologist, to be able to pursue this subject to any advantage to mankind.

954. And therefore it would be an infliction of purposeless distress for any other class of persons to make these experiments ?—Entirely, so much so that I should think it entirely unjustifiable in myself to do anything of the kind, though for so many years I was engaged as teacher of physiology. My hand is out of practice in the subject, from the fact of my work lying in other directions. I should think it simply unjustifiable in me to perform a single experiment of the kind. I should send it to an expert, and I should say " I rather think you may find such and " such a point capable of elucidation in such a way; " will you see to it ? " but I should not dream of doing it myself, because I am incompetent.

955. Is there anything else which you desire to add ?—I have in my last remarks alluded to the great question,—the question of the propriety of inflicting pain upon living animals, for the purpose of acquiring all the knowledge that we can of the structure of ourselves or animals. I will only add that I cannot look upon any inquiry of this kind excepting as a part of the whole question of the structure of the world in which we are placed, and of our intellectual and moral and religious nature. I look upon investigations into the structure of animals as part of the whole question of our Nature. People who cannot agree upon the existence of a future state, or upon the value of Christianity, and upon what therefore is desirable for keeping society together by the higher kind of morality, in fact people who do not know what their aims are with regard to this life or the next, are not very likely to come to an agreement as to the precise relations of man to the sufferings of the other animals placed in the world with him. At all events I look upon this subject in the light of humanity at large.

956. (*Lord Winmarleigh.*) You said in answer to a question of Lord Cardwell's, at the commencement

Mr. H. W. Acland, M.D., F.R.S.

12 July 1875.

of your evidence on this subject, that your approval of experiments on animals depended upon the question whether it is essential to extend human knowledge in that direction. I have collected from your subsequent answers that you do believe that it is very desirable to continue to extend human knowledge in that direction?—I believe it to be my duty as a physician, and the duty of the profession of medicine throughout the world, to do everything that we can to mitigate human suffering, to prevent disease, and to make the human race, especially the nation to which we belong, as strong in body and mind as we can; but not to do it in wanton and immoral ways, and not to do it for fancies of any kind, nor for the purposes of scientific ambition.

957. But subject to those limitations, you do consider that experiments on living animals are desirable? —Yes, as part of investigation, though I do not think that for the purposes of advancing the knowledge of medicine experiments on animals are the most important means.

958. Your observation applied then simply to physiological experiments?—To physiological experiments. I declined to sign a memorial lately in which it was stated that the progress of medicine depended mainly upon experiments on animals; I do not think it does, and therefore I declined to sign the memorial.

959. But you do believe that the progress of medicine is assisted by them, and beneficially assisted by them?—Yes.

960. Would you state who are the parties in Oxford under your control who are authorised to make these experiments in your own school of medicine? Is there any person except yourself who is authorised to make these experiments?—There is no person authorised at all.

961. You never allow a pupil or any person of an inferior position to yourself to do it?—I must not put it in that way. You must bear in mind that I have nothing to do now with the anatomical department; I have left it entirely. I spoke of my colleague, Dr. Rolleston, and I said that personally I had no doubt that he did not allow it. But there is no one to authorise him either to do it or not to do it.

962. But when you were in the position which Dr. Rolleston is now in did you allow any person but yourself to perform these experiments?—I never did allow anyone except my highly-skilled assistant, nor do I think he would.

963. (*Mr. Hutton.*) Did you not say that you were anatomical professsor formerly?—I was the sole teacher of anatomy and physiology in Oxford all the time that I was the teacher.

964. (*Lord Winmarleigh.*) Were all the dissections that you made, chiefly or altogether made under anæsthetics?—These dissections were dissections of dead animals almost entirely.

965. But when it was an experiment on a living animal was it done chiefly under anæsthetics?—I think that all the preparations to which I have alluded that were got from living animals were got from animals that were killed for the purpose.

966. I collect from what you have stated that you would not have made an experiment, except under great necessity, which inflicted pain without anæsthetics?—Certainly not.

967. You have alluded to a discussion which has taken place in the medical profession, and which was stopped in consequence of the issuing of this Commission. Will that discussion go on now before the report of this Commission?—The Medical Council sits generally once in the year, and in consequence of this Commission sitting the discussion was not brought forward, and of course it will depend upon circumstances whether it is relevant or desirable to bring it forward when we meet again. The Medical Council will sooner or later have to consider to what extent the subject of practical physiology, as it is called, should be required of all students, and no doubt the Medical Council would be materially influenced by the report of this Commission.

968. (*Mr. Forster.*) I understood you to say that you certainly would not allow inexperienced persons to try these experiments on living animals?—The only possible justification for that would be that it was desirable to train them to do it; because of course in order to get experience people must begin. Now I do not think that it is at all necessary, and therefore it is not desirable, that the average medical students, who have no chance of being experts in this matter, and who never will be, should go through all this.

969. And I think I also understood you to say that you believed, at any rate you trusted, that in England the men of science who were fitted to try the experiments would do them with care and inflict as little suffering as possible?—Certainly.

970. Has your attention been called to a handbook for the physiological laboratory, lately published by Dr. Klein, Dr. Sanderson, Dr. Foster, and Dr. Brunton?—Yes.

971. Does not that book rather suggest to students— "workers," as they are called in the preface,—how they can in their own study best get to understand physiology?—I suppose the object of that book is in a great measure to explain to learners how they may themselves pursue these experimental investigations.

972. Would you just turn to page 108. Opening it by accident at that page I find a mention of that experiment upon the circulation of the blood, as illustrated by the frog, to which you referred; and there it is said how the mesentery can be laid bare; and it is suggested that that should be done under the operation of curare. Do you know what effect curare has?—Upon the whole I do. There are some niceties about the employment of it, but upon the whole the effect of it is to destroy voluntary motion.

973. Do you feel confident that is destroys sensibility?—I cannot answer that absolutely; I do not know.

974. Then just looking at that experiment, would you not think that it was very questionable to suggest to practical students that experiment merely under curare?—Of course the object of that is to produce stillness in the animal; that is the intention.

975. Will you turn to page 113. I observe that there is there a "demonstration of the lymphatic system of "the diaphragm by injection." It is stated that a middle sized rabbit has been kept from 16 to 20 hours without food, and then it was bled to death in a process of three hours and a half. Do you not think that experiments such as those require to be under some legal regulation?—I have already answered very fully, I think, on that subject; I think that experiments on animals which are not calculated to elicit new truths, and which are not actually necessary for the education of competent medical men, ought not to be performed. But whether that is to be secured by legal enactment is another question on which I have spoken, I think, quite fully; I have a doubt about it.

976. (*Mr. Erichsen.*) As President of the Medical Council you have the general supervision of medical education in Great Britain and Ireland?—The Medical Council has, but as President I have not.

977. And you have the supervision of the Medical Council?—No; I am President of that Council, and the Medical Council has the supervision of medical education.

978. And you have stated that a great part of the development of these physiological investigations of late years has been owing to the requirements by the directors of medical education of the establishment of physiological labatories for the teaching of practical physiology?—Physiologists have demanded these laboratories.

979. And has it come to your knowledge as a member of the Medical Council, that in these physiological labatories students (I mean young men in *statu pupillari*—I do not mean advanced men who are studying for their own purposes, but young students,) practise experiments, either under super-

Mr.
H. W. Acland,
M.D., F.R.S.

12 July 1875.

vision or without supervision, on living animals?—I think I may say that the Medical Council has not had this subject before it. It has only existed for a very few years; it has had a vast mass of work to do in the way of organising medical study generally; but this detailed subject has not been brought before it, as I stated before. It would have been brought before the Council this year for special consideration in framing some new regulations which we were engaged upon, had it not been for the sitting of this Commission. To that I would add, that I have no doubt that next year as it happens this subject must be considered, because the Council is about to revise the whole of the details of education and examination throughout the country, and it will be quite necessary (I may presume I think to say this without consulting the Council on the subject) for the Council to decide whether in examinations practical experimentation is to be required of candidates for licenses or not; and if the Medical Council does not require that candidates for licenses and diplomas should themselves perform such experiments, you may be quite sure that no pass candidates will acquire that knowledge. But then a further question would arise, which would not be within the province of the Medical Council,—how far these subjects should be made a branch of examination for honours; but Dr. Rolleston will, I hope, speak on that point.

980. Can you tell me from whom the recommendation of the establishment of these physiological laboratories emanated? Was it from the Medical Council or from individual teachers, or was it made by the different medical corporations and examining bodies?—I have no official knowledge on that point, but I believe that I am right in saying that the laboratories of practical physiology have arisen in consequence of the zeal and earnestness of the teachers in the department of physiological science, who have been endeavouring as years have gone on to provide for their students all that they believe to be necessary for the mastery of biological knowledge. When I was a student myself, the use of the microscope was not taught in St. George's Hospital in the physiological laboratories and hardly ever in the wards; and now in consequence of the increase of knowledge and the increase of appliances, all the apparatus is gradually being provided which seems to elucidate the physical sciences, and to assist in experimentation.

981. You made a most important distinction, and one that has been made to-day for the first time before this Commission, that between medical men and a body of scientific men who are growing up in this country who are not medical men, but who are yet devoted to the study of the sciences connected with the operations going on in the living body, who are physiologists and biologists; and it is your opinion that the great progress that has taken place in the development of physiological work is owing to these men working at their science as a science, independent of its direct application to the purposes of alleviating human suffering?—I think that speaking roughly of the history of human knowledge in this direction, the pursuit of biology was formerly generally confined to medical men, that is to say, to a body of men whose first object in life was the alleviation of suffering or the prevention of disease.

982. Might we say practising medical men?—Well, I should say the medical profession generally; they were generally practitioners; but in the progress of knowledge the extent has become so vast that a man now, as is well known to the whole members of the Commission, can hardly master the whole of any one of the physical sciences, therefore they have been subdivided amony different inquirers; and consequently there has arisen a race of professed physiologists, whose business has not to do with the alleviation of suffering, but has to do with research as to the mode of construction of living beings throughout the world, and all that will elucidate that.

983. Referring to such men as you have mentioned, Sir Benjamin Brodie, Dr. Hope, Sir Charles Bell, Sir Astley Cooper, Mr. Travers, Mr. Lawrence, and a number of men of equal or similar position in the profession, the experiments which they performed were performed with a definite object to elucidate some point that was directly connected either with the pathology of diseases, or with a surgical operation and its treatment, or in some way or another they had a direct bearing upon the alleviation of human disease and suffering?—I could hardly lay that down with the precision which you do, because I think that although that was the starting point of all their inquiries, it would really be unjust to those great names, looking upon them as some of our great intellectual lights of different epochs, to say that they had not a love of knowledge and research as such, because I think that Sir Benjamin Brodie essentially had; but his starting point and the centre of his whole life was the acquiring knowledge for the direct alleviation of suffering, and the benefit of mankind in that way. At the same time, however, he had a great scientific instinct as John Hunter had If you look at the single case of John Hunter you will see at a glance what happened with him. He being a surgeon thought that he could aid humanity by dissecting over the whole range of the animal world, and he did so; but he started with his investigations into life and generation and development, and so forth, for the purpose of discovering how he might alleviate human suffering. Then he pursued his subjects with a purely scientific aim. But it is one thing to have that object of alleviation of human suffering as the basis of your aim and character, and it is another thing to be entirely separate from it, and to be pursuing these investigations from a simply intellectual stand-point. I do not say that in any way as criticism, but merely as fact.

984. And these men you have mentioned had that as their basis?—It was their basis no doubt.

985. And their labours were recognised, and were encouraged by learned societies in this country. For instance, the Royal Society awarded the Copley medal to Sir Benjamin Brodie for experiments on living animals?—Yes.

986. The British Association for the Advancement of Science has, has it not, at various periods made advances of money for the purpose of defraying the cost of experiments on living animals to elucidate certain points?—Yes; and the Royal Society's transactions and various scientific publications for the last two centuries are full of experiments and investigations bearing upon this subject, dating at least as far back as Harvey; but with definite aims, which I would say upon a large scale are becoming, as time goes on, less necessary, because the more salient points and the greater questions are becoming understood, and the greater number of the experiments, therefore it is quite unneccessary to repeat.

987. I suppose we may take it that you would object to the repetition of experiments for the purpose of verification where those salient points have incontestably been decided?—Yes, I think so.

988. And for the purpose of demonstration in classes before students you have not found it necessary, as a reader of anatomy, to perform experiments upon or to dissect living animals?—At the time that I was lecturer on anatomy the subject had not attained the magnitude that it now has. Such a book as Klein's did not exist. Knowledge has extended very largely in this direction in the last 25 years, and there is therefore much less need to show these experiments now; but I did think it right when I was teacher to show, on more than one occasion, a series of discoveries, among the most remarkable that the world has ever seen, namely those of Martin Barry upon the development of the mammiferous ovum. It was an exceedingly delicate and difficult operation, which then was perfectly new to the world. The exhibition of this mammiferous ovum implied the death of an animal.

989. (*Mr. Forster.*) But it did not imply the vivi-

Mr.
H. W. Acland,
M.D., F.R.S.

12 July 1875.

section of the animal ?—No. And that was not done with suffering. This is, I think, a very good illustration of that. I did it partly for my own instruction. I thought it right that I, being a teacher in anatomy, should see this, which up to that time had never been understood in the world before. I thought it right that I should show it to a certain number of select students, some of whom are now living, none I think medical men, but eminent men in various walks of life; but I should have thought it wrong to make it a common practice even to sacrifice a rabbit for that purpose. That may be foolish in me, but then I have always had a horror of dissection, though I have done a great deal of it. I exceedingly dislike killing animals for it, and should not do it except from necessity.

990. (*Mr. Hutton.*) Dr. Humphry in his evidence said that the line of demarcation between experiments that were desirable for the purpose of demonstration and those that were desirable for a physiological class was quite an evanescent line. He gave us the impression that although ordinary practitioners in the present state of education need not go through a physiological laboratory, it was desirable that all students that were thoroughly educated should do so. Now have you an opinion to give on that subject ?—The best short answer perhaps that I can give to that is this,—that I think those who have seen the actual working of the mechanical structures of living beings during life have quite a different conception of them from those who have only seen them in the dead body. I do not think that anything made a greater impression upon me during my youth than accidentally while fishing in a trout stream in Devonshire opening a small trout which I had caught, and cleaning it as it is called, that is taking the viscera out and having in my hand the palpitating and acting heart for at least half an hour after it had been removed. That filled me with such a sense of wonderment, and so impressed me with the beauty of these internal structures, that probably it was the cause of my being in this room at this moment. Now a person who has only seen these structures after they are dead and their use gone does not know anything about them at all, in the sense that a person does who has seen these wonderful phenomena. Therefore I say that some of them ought to be seen during life.

991. (*Lord Winmarleigh.*) The circulation of the blood was discovered in exactly the way in which you have described, your observing the heart of the fish, was it not ?—It is not quite certain what argumentation led Harvey to that, whether it was the observation of the living structure or the contemplation of the dead structure.

992. (*Mr. Hutton.*) I understood you to object to experiments for the mere discovery of fresh knowledge, apart from their subsequent influence upon the healing art, or rather that you have great doubts about experiments for the mere purpose of extending knowledge ?—I did not mean to express myself quite so strongly as that. I drew a line of demarcation between knowledge which I obtain for a subsequent benefit to mankind, and knowledge which I obtain merely for knowledge sake. They are two things. I do not presume to say whether one is really inferior to the other; I did not wish to express an opinion on that point. I merely drew a distinction between them. I have not the slightest doubt that it is right in me to take a step which will enable me to save mankind from suffering and pain if I can, if I have a clear view that that is the way to do it. But whether it is right in me to put animals to suffering and death in order to add to my range of knowledge, if I could know beforehand that it could do no good to man, is another question. But it would not be at all right for me to throw any disparagement on the pursuit of knowledge for knowledge sake; it is the last thing that I would wish to do; but I draw a line between them, because I think that they are two distinct vocations and two distinct dispositions of mind.

993. But you would think that the one would require more careful supervision and control than the other. You would be more anxious to restrain experiments for the mere prosecution of science than those for the alleviation of human suffering ?—I should personally, because I am a practical physician. I am quite certain of the value of prevention and cure of disease. But it is impossible to draw an exact line between what knowledge is and what is not likely to be practically beneficial.

994. You were referring to those experiments of Brown-Séquard's. In a paper which I have in my hand he says: "My watching over guinea pigs has been on such a scale (at one time before the siege of Paris I had 584 in my laboratory) that I can say I have had many and many thousands under observation from 1843 till now, a period of more than 30 years." Would you not say that if experiments are attaining to anything like those dimensions in England, they would require very careful supervision to see that the interests of the victims were protected to some extent ?—I should be very loth to sanction anything which added to the suffering in the world, either in men or in animals; and I very much wish that the public sense of right would take a great deal more pains than it does to diminish unnecessary suffering in the world. I wish to say nothing here on the subject of the various field sports, and what pass as innocent amusements; but as a matter of fact the amount of needless suffering in the world caused in other ways is far greater than the amount of suffering caused by such a person as Brown-Séquard; and however unpopular that opinion may be, it is simply a statement of a fact, and therefore I think it right that I should say it.

995. You would hardly say, I suppose, that any one sportsman had given pain to that extent; that I suppose is clubbing the work of a great many sportsmen ?—I should be very sorry to say he had not.

996. Brown-Séquard's is a case of a most distinguished man, of the very highest scientific power; but if the same class of experiments were to be conducted by any man of inferior genius surely they would be liable to the greatest possible abuse ?—Certainly, and they would be perfectly useless.

997. But who is to draw the line, if there is to be no kind of legal control in the matter as to the power of a man to prosecute with advantage experiments of this kind ?—I should feel myself to be a very imperfect judge of that; but I do think that the general opinion of scientific men, and especially of the medical profession, rings so true upon this matter, that upon the whole, especially now that the attention of the world is being thoroughly drawn to it, the abuse by persons experimenting will be really very small; I should think so at least.

998. Do you speak after a thorough study of this handbook edited by Dr. Sanderson, or only with a general knowledge of it ?—I have not thoroughly studied that book, because I am not at work in that department.

999. It seems to me that a very large class of the experiments of this kind in this handbook are purely demonstrative; that they are intended to be repeated by students, and are actually repeated by students in most of the laboratories where this handbook is used ?—I quite agree to that. I have already said that on the continent this practice of experiments upon living animals is carried to a very great extent; and also that, as Mr. Erichsen has put it to me, the practice has grown up and is growing up in this country among teachers, partly in consequence of the additional knowledge which we have got, and the additional zeal of an increasing number of persons whose vocation it is to study living beings; and I illustrate that by saying that I have no doubt that there are many persons who look upon living beings merely as a form of matter in a particular kind of operation, and who simply consider it their business to investigate them, and learn anything they can about them. That is a new phase of modern thought and a comparatively new phase of investigation, one which leads us necessarily into very serious conceptions and questions of

Mr. H. W. Acland, M.D., F.R.S.

12 July 1875.

the nature of our whole being and moral responsibilities. It is to me part of a great moral and intellectual question bearing on the very foundation of human society.

1000. I understood you to say that you did not object to the Anatomy Acts; and they are only necessary for the protection of the feelings of relations, I suppose; they do not really prevent any kind of suffering, except to the feelings of the relatives?—Quite so.

1001. Surely then, if you do not object to the Anatomy Acts, you would be favourable to Acts which gave you the same kind of security on behalf of creatures which suffer in a way which dead bodies cannot do?—I think the cases are very different. The Anatomy Act was necessary in order to provide subjects for dissection for the ordinary education of medical students.

1002. But surely you would take the case for an Act in this matter as stronger than the case for the Anatomy Acts, so far as those Anatomy Acts were to protect the feelings of the living, and not simply to procure subjects for the anatomists?—I think that the whole answer I can give to that question is this: that if the case is made out that there is wilful and wanton and unnecessary cruelty on the part of the scientific teachers, then a case is made out for abating that. That I entirely agree to. But whether the way to abate that is by putting these eminent and cultivated persons under the control of the law in an ordinary way, or whether or not the Royal Society or other persons should have their attention drawn to it, with a view to their considering in what way these studies should be controlled, is another question; and I did not feel it to be desirable that I should express a definite opinion about it.

1003. (*Lord Winmarleigh.*) You leave that to us?—Yes, I feel it to be my duty to leave it to the Commission. I believe that it is a very good method which is adopted by the British Association, to place money grants in the hands of a committee, to be employed by particular persons for particular objects; and *mutatis mutandis* I could well imagine, at all events with any public grants, that some such method as that should be adopted; because money is voted at the present moment out of the public funds for purposes of this kind, or at all events allied purposes.

1004. (*Mr. Hutton.*) That does not suggest restriction, does it, but only fresh facilities?—Yes.

1005. With reference to Sir Benjamin Brodie's experiments, were not those experiments on dividing the vagus nerves both painful and fruitless; I mean those experiments with regard to digestion. There is an account of them given in a pamphlet before me, which gives the impression that they were both very painful experiments and quite fruitless?—Without referring to them in detail I could not give a scientific answer to that question, but I would say at once that supposing that were to turn out to be the case, that would be no objection whatever to such experiments in the hands of a really scientific man like Sir Benjamin Brodie, because it is clear in the nature of the case that an experiment which is to decide upon a point may sometimes decide that in that direction progress is barred, and nothing more can be done. It is rather a remarkable thing with regard to all great scientific men, that they very seldom have undertaken investigations which have not come to a successful issue. There is a peculiar instinct in the minds of men like John Hunter, or Sir Humphry Davy, or Sir Benjamin Brodie, or any great investigator in any department of science, which so guides them that they very seldom begin a research which does not come to a useful issue; they have an instinct which tells them just the point which is capable of further devolopment, and you will find that failures are very rare in their case; and that is one reason why inferior people are useless, because they have not that instinct and they do not know the precise point of science which is capable of further development, and so they waste their own time and other people's too.

1006. (*Chairman.*) And inflict purposeless suffering?—Suffering which produces no result.

1007. And suffering which a greater amount of knowledge on their part would have prevented?—Yes.

1008. (*Mr. Hutton.*) Do you not think very able men indeed, prosecuting experiments with a purely scientific end like Dr. Klein, would be apt to suggest a great many experiments which would be quite fruitless?—Fruitless very likely for the purpose of alleviating human misery, but not fruitless for the object of clearing up a definite point of knowledge.

The witness withdrew.

Sir W. Fergusson, Bart., F.R.S.

Sir William Fergusson, Bart., F.R.S., called in and examined.

1009. (*Chairman.*) You are Sergeant Surgeon to the Queen?—Yes.

1010. And surgeon to King's College Hospital?—Yes.

1011. And a Fellow of the Royal Society?—Yes.

1012. Has your attention been drawn to the subject which this Commission has been appointed to consider?—Yes, it has.

1013. Have you had much personal experience about it?—A great deal in my earlier life.

1014. Not so much latterly?—Not so much latterly.

1015. What is your opinion generally speaking upon the subject as to its neccessity or utility?—I have an idea that a great deal that has been done has been of service in regard to physiology and human knowledge, but that it has not been of that immense value to human nature that some claim for it.

1016. Are you of opinion that there has been recently a great development of the taste for this sort of investigation?—Yes; I am impressed with that opinion.

1017. And are you of opinion that that taste has been accompanied by a corresponding amount of utility?—No; I doubt if there has been a corresponding amount of utility.

1018. Now are experiments which involve suffering carried to a greater extent than they need be?—I think so.

1019. In what respects?—There is continued, and, in my estimation, useless repetition. When once a fact, which involves cruelty to lower animals, has been fairly recognised and accepted, it seems to me that there is no necessity for a continued repetition of experiments to display that fact.

1020. When an experiment has once decided a question, you think it should be left there?—Yes; unless there is some good reason for reviving the subject.

1021. Unless there is some reason to think that some new element has come under view which requires a new experiment to solve it?—Quite so.

1022. Now with regard to those new experiments, is it a matter for considerable judgment whether they ought to be tried or not?—Yes; I think it requires a very high style of judgment to do a rational experiment under such circumstances.

1023. And that therefore the number of persons who ought to perform such experiments is at any rate very limited?—Comparatively limited.

1024. Can you give us any instances in surgical history which would illustrate these positions?—Such instances as I can think of seem to me to have been after the fact more than prior to the fact. Some of the most striking experiments that have been performed on the lower animals with reference to surgery have really been already performed, not experimentally, but on the best judgment, on the human subject, and proved on the human subject; and therefore there is

Sir W. Fergusson, Bart., F.R.S.

12 July 1875.

scarcely any necessity for the repetition of such operations on the lower animals to prove the fact. In recent times there has been more said and written to catch the public mind than there used to be on the subject; and I have observed that frequently certain operations in surgery have been referred to as having been developed in consequence of experiments performed on the lower animals. Now, John Hunter, who was one of our greatest physiologists, and allowed to be one of our greatest surgeons also, and may be said to this day to stand at the head of what is called scientific surgery in this country, is specially celebrated for an operation which he devised on the arteries. That operation for 60 or 80 years stood as one of the most brilliant in surgery; and in so far as I have been able to make out (and I have inquired into the subject), Hunter's first experiment, if it might so be called, was done on the human subject, and it was long after he had repeated his operation on the human subject and others had repeated it, that the fashion of tying arteries on the lower animals originated or was developed. That fashion was quite justifiable at the time; it is no longer now justifiable; but in regard to the surgical aspect of the case, the experiment might have been left entirely untouched, for Hunter had already experimented and developed the fact on the human subject.

1025. Then in short in this particular case the experiments that were tried on living animals did not establish the fact; they were only useful, if at all, for illustrating it *à posteriori*?—Quite so.

1026. Now have the great performers of these painful experiments on animals been generally great surgeons? — No, I am not aware of any great surgeons having been very great experimenters on the lower animals. In this country we think that the experiments which Sir Astley Cooper performed on the lower animals were interesting; but they were some of these very operations which I have referrred to, after the development of the operation on the human subject. Of course he is one of those great surgeons who did perform such operations satisfactorily for the time, but I am not aware that any very expert operator on the lower animals has made himself thereby an expert operator on the human subject; nor am I aware that a great operator on the human subject has ever prided himself on being a good operator on the lower animals.

1027. We have heard the name of a very celebrated surgeon, Mr. Syme; what was his practice?—My recollection of Mr. Syme's scientific investigations leads me to think that his operations on the lower animals were chiefly on dogs and rabbits, to ascertain certain views regarding the life and death and growth of bone; he used to perform a number of operations of that kind, but though the detail of them was interesting enough at the time, I am very doubtful now whether these experiments had any special beneficial influence on the practice of surgery.

1028. Mr. Syme was himself very unwilling to perform these experiments, was he not?—He lived to express an abhorrence of such operations, at all events if they were not useful. I think at the time he performed them he was willing enough, because he thought that he had a great object in view.

1029. But his ultimate authority was strongly on the other side?—Strongly on the other side, as expressed in a special report of his own in association with some gentlemen interested in veterinary surgery and physiology.

1030. Have you a copy of that?—Yes, I have got a copy of it. About the year 1867, Mr. Syme and other gentlemen had been asked to give their opinion regarding the subject of vivisection, and there is a report published in the 40th volume of the "Veterinarian," 1867, to this effect: "We have great " satisfaction in publishing the following important " protest: 'We the Court of Examiners for Scotland, " 'of the Royal College of Veterinary Surgeons, " 'desire to express our opinion that the performance " 'of operations on living animals is altogether un" 'necessary and useless for the purpose of causation. " 'James Syme, Chairman, James Dunsmure, M.D., " 'President of the College of Surgeons in Edinburgh, " 'J. Warburton Begbie, M.D.; John Lawson, Pre" 'sident of the Royal College of Veterinary Sur" 'geons; B. Cartledge, M.R.C.V.S., Member of Coun" 'cil of R.C.V.S.; William Cockburn, M.R.C.V.S.; " 'William Robertson, M.R.C.V.S.; Charles Secker, " 'M.R.C.V.S.; James Cowie, M.R.C.V.S. I fully " 'concur in the above, John Wilkinson, Principal " 'Veterinary Surgeon to the Forces.'" No man perhaps has ever had more experience on the human subject than Mr. Syme, and I believe, from knowledge that every man is acquainted with, that he investigated by experiments on living lower animals, partly with a view of developing features in reference to the human subject, but more in fact with regard to physiology than with regard to practical surgery, and I myself have a strong opinion that such an expression coming from Mr. Syme (and he must have passed the middle period of life at that time), was a mature and valuable opinion.

1031. Did I rightly understand from you just now that your own opinion in mature life was much less favourable to these experiments than it was when you were young?—Yes, because I had not the same grasp of the subject at that time. I was more perhaps influenced by what other people had done, and by the wish to come up to what they had done in regard to such matters, but the more matured judgment of recent years has led me to say to myself now that I would not perform some of the operations at this present time that I performed myself in earlier days.

1032. Do you think that these experiments on the lower animals have contributed very much to mitigating the pain and removing the suffering of the human race?—I do not think that they have. I think they have been of great value in many respects, but certainly I cannot think that they have led to the mitigation of pain in the human subject.

1033. But that in point of fact they have been much more pursued by persons who are not practical surgeons than by persons who are?—Decidedly. Even with reference to the subject of chloroform the best and chief experiments were made on the human subject; all the experiments on the lower animals have been done since the experiments were conclusively applied to the human subject.

1034. When chloroform was introduced by Sir James Simpson he tried many of the experiments on himself, did he not?—Yes, he did when he was trying the effects of chloroform. Of course anæsthesia was devised prior to that time.

1035. Are you able to tell us whether there is reason to believe that experiments upon animals, on the supposition that they may be necessary, are performed with all the care and all the regard to the sufferings of the animals that there ought to be?—I could not give a precise answer to that; but the impression on my mind is that these experiments are done very frequently in a most reckless manner.

1036. In a manner that, if it were known to the public at large, would call for interference on their part?—Yes, and would bring the reputation of certain scientific men far below what it should be.

1037. We have been told that, speaking generally, experiments of this kind are performed with the greatest possible consideration for the animal, and with the greatest indisposition to inflict at least protracted suffering. Do you believe that to be the case?—Gentlemen may fancy that, but I do not think that they fulfil that idea. Indeed I have reason to imagine that such sufferings incidental to such operations are protracted in a very shocking manner. I will give you an illustration of an animal being crucified for several days perhaps; introduced several times into a lecture room for the class to see how the experiment was going on.

1038. Do you believe that to be done not only on the continent of Europe but also in this country?—

Sir W. Fergusson, Bart., F.R.S.

12 July 1875.

I believe it to be done in this country, from what I have heard.

1039. (*Mr. Erichsen.*) For what purpose?—Some physiological experiments which the teacher might be interested in at the time.

1040. (*Chairman.*) You think that if the public really knew what was actually going on in this country at this time they would expect an interference on the part of the Crown and Parliament?—I do think so, just as much as with reference to the disinterring of dead bodies years ago.

1041. Have you got in your mind any particular mode in which you think the Crown and Parliament could usefully interfere?—In a very vague way certainly. I think it could only be done by a judicious representation to men engaged in science that they must be careful how they resort to such experiments, and how they encourage the performance of them by those who are younger and less informed than themselves.

1042. You have just now referred to the subject of anatomy. Do you think that any interference with experiments upon living animals of the nature of that which was introduced in regard to anatomy could be usefully applied?—I believe there might be some sensible jurisdiction, but it would be a difficult thing to point out one to please all parties.

1043. But without attempting that impossibility, do you see your way to some interference with these experiments?—I think that an expression of some views from the Government and from the Houses of Parliament would have a very wholesome effect; that a man would then very likely run the risk of losing caste and character if he went beyond certain bounds.

1044. For that purpose it would be necessary, would it not, that there should be publicity?—Publicity is much better than privacy in regard to these matters.

1045. Would you see any objection to the application to this subject of the same general enactment as has been applied to anatomy?—It would be a much more difficult subject to legislate upon; the field is so extensive. There is a large amount of thought associated with the matter, giving rise to features that we cannot connect with the mere taking bodies from the grave and dissecting them. Men of a very superior stamp might have thoughts in their minds, and the desire to develope these thoughts by experiments that really would be of great value to the human subject, and it would be I think a great pity that such a man should be entirely trammelled. But if you had reason to think that a man of enthusiastic mind was indulging too freely in these thoughts in that way, it might be well to bring him to his senses, to show him that he was only working in ignorance as it were.

1046. Should I rightly represent your views if I said that you think there is some great need for a remedy; but that the application of that remedy is difficult?—Yes.

1047. It would require therefore great consideration and care?—Yes.

1048. Nevertheless, that if the public knew all that is to be known on the subject, they would be likely to demand some remedy?—Yes; I think they would.

1049. (*Lord Winmarleigh.*) You have stated that you consider that experiments involving cruelty to animals have been too frequent, and that they have not led to the mitigation of pain, generally speaking; but I presume you did not mean to say that they have not led to the successful treatment of complaints, or the mitigation of human suffering at all?—With reference to that I may perhaps speak more confidently regarding surgery than other departments in my own profession, and in surgery I am not aware of any of these experiments on the lower animals having led to the mitigation of pain or to improvement as regards surgical details.

1050. But we have had statements here by a very high medical authority that there were several branches of medical science which have been entirely ascertained by means of these experiments. We have had brought to our attention, for instance, the circulation of the blood, and the action of the heart?—Of course everyone admits those; but then that is a bygone thing.

1051. And on the liver and the kidneys and the nerves, we have been assured here that very great knowledge has been obtained, which could not possibly have been obtained except by vivisection?—Well, I suppose we must admit that; but I have no very strong impression on my mind as to the great value of some of these experiments. I do not think, referring to the most recent experiments that have been made, that you can form a very accurate opinion as to the actions of nature from looking through the walls of the abdomen at the liver. You get a window cut in the side of the abdomen, and get the gall bladder laid open, and you look at it, or a physiologist looks at it, and watches it a certain number of hours or days; but the animal is put into such an extraordinary condition by all that has been done, that I cannot say that I have very great confidence in the results of such an experiment.

1052. But do you think that the same knowledge would be obtained by operations on the human body?—No, certainly not; but a great distinction should be drawn between the two, I think. Very often certain operations are performed on the lower animals, and these experiments are used in a way that they never would be used in the human subject.

1053. (*Mr. Forster.*) What you meant by your answer I suppose was, that the abnormal conditions of the experiment in which the animal was put, made it very doubtful what was the advantage of the experiment?—Exactly. The opinion in my mind with regard to that might be illustrated from what we have all felt. At the beginning of the week you have felt as well as you have ever done in your life; at the end of the week you are knocked down by some kind of fever; and then every function in your body is disturbed, and there is nothing in accordance with normal or healthy nature. Now for my own part I say that an experiment performed on my body at the beginning of the week, and one performed at the end of the week, under such circumstances, would be totally different and would lead to different results. There would not be that kind of precision in the results that ought to be considered essential, unless indeed you are experimenting to ascertain the difference between health and disease.

1054. (*Lord Winmarleigh.*) With the opinion that you hold on the subject, would you think it safe to abolish altogether experiments on living animals with a view to obtaining thorough surgical or medical knowledge?—No, I certainly would not go that length of restraining rational men from doing that which they thought right; but I would enjoin great caution.

1055. Supposing that this Commission was to recommend certain restrictions upon these experiments, could you suggest to us any mode by which you could distinguish useful and necessary experiments from those which you think involve cruelty, and which are of no use to the human race?—In general terms I have done that already; but in regard to other ways, I think you must still leave a margin for a man's judgment, and if he chooses to display very bad judgment he must just suffer as other men do who display very bad judgment in all the ordinary transactions of life. But it would be well that there should be some kind of superintendence, such as is indicated by you; let the man know that if he goes to excess he will fall into a low caste.

1056. That is to say, you would leave it to the impression made on the public mind, and not to any legislative enactment. Does not your suggestion amount to that?—Yes; that is a fair view of it. I might give you an illustration of that. Perhaps it might be disputed, but my own idea is (and Mr.

Sir W. Fergusson, Bart., F.R.S.

12 July 1875.

Erichsen, perhaps, would confirm me in that view), that so far as the treatment of human beings in hospitals is concerned (I say it with all respect to continental practitioners), there is, so to say, more humanity and kindness displayed in English hospitals than there is in hospitals abroad, in certain countries abroad at all events; and that I attribute largely to the circumstance that every man practising in an English hospital is largely amenable to the observation and opinions of those who take interest in these hospitals; whereas in a foreign hospital, so far as I can understand, the man is himself the sole arbiter. He may do what he chooses and there is nobody to interfere, and it will not injure his position in social life or practice; whereas if a man in this country were to get a character for roughness and rudeness, and want of courtesy to his patients, to a certainty that man would soon feel that he had lost caste in the general community, and losing caste he should not have that position that he otherwise should.

1057. The object of this Commission is first of all to ascertain what is the extent to which what is called vivisection is carried on in this country; the second object is to ascertain what is the way in which it should be treated in the future. Now I collect from what you have just stated to us, that you are opposed to legislation on the subject. Is that so? And would you prefer to leave it to the influences which you have just mentioned?—There might be, I think, an opinion expressed on the subject by the great authorities in the country, but I should be very reluctant to coerce scientific men to give up their investigations. They are considered of very much importance by many.

1058. You would not, for instance, recommend that any particular officer should be directed to attend on every occasion when such experiments were made?—No, I think it would be a most offensive thing to men of science in this country that that should be done.

1059. You would be satisfied then if this Commission were to express its opinion very strongly on the subject, and leave it for the consideration of the public?—That would come up to my views and feelings on the subject.

1060. (*Mr. Forster.*) The proposition has been made that the legislation should bring in the principle of licensing, that is to say, licensing men who are supposed to be qualified for making experiments, to try them. Has that suggestion come before you?—I have heard it.

1061. What do you think about it?—It is very questionable.

1062. When you say that high authorities should express an opinion on the subject, you mean the Legislature?—Yes, or the Government.

1063. But you think that it should be a mere opinion, without attaching any penalty to persons who went contrary to that opinion?—I do not see my way to a penalty, excepting that penalty that I have referred to again and again,—that a man must suffer in public estimation according to his acts and deeds.

1064. Is it not the case that a great many of these experiments are tried by men of science in their own apartments?—I believe so.

1065. Then public opinion would not reach those men, would it?—Yes, it would have its effect in a short time.

1066. You think it would be known that they did try the experiments?—Yes; of course there is the Society for the Suppression of Cruelty to Animals, they would interfere; just in the same way as when a person ill-uses one of his own family, if that goes on largely it is found out by the public at last, and the person suffers accordingly.

1067. Are you aware that the present Cruelty to Animals Act is not supposed to apply to these experiments because of the definition of "animal?"—Yes, I am aware of that feature.

1068. Do you see any objection to enlarging that definition, so as to include wild animals?—It would be a great advantage I think to do so.

1069. So as to throw, as it were, the *onus probandi* on the man to show that he had a proper object in the experiment?—Quite so, and to make him aware that the life of the wild animal is as precious to itself as the life of the domestic animal.

1070. The fact that that might in some degree hit the sportsman would not be an argument against it, you think?—No, that is the poor device of some people to stop all these inquiries; I do not think it is an argument at all.

1071. You have studied anæsthetics a great deal, I suppose?—Yes.

1072. Do you know anything of this Wourali? Do you consider it an anæsthetic, or not?—Forty years ago I used to use it frequently as a poison.

1073. Do you think it is an anæsthetic?—I am not aware that we have the smallest proof to that effect.

1074. My reason for asking that is that in this handbook of physiology there are a great many experiments described, generally speaking, at least often they are suggested to be made, under the influence of this Wourali. You would not consider that that could be depended on as an anæsthetic?—Certainly not. My recollection is to the effect that it generally killed outright, and very speedily.

1075. I suppose the fact that it is in itself a poison prevents the question being solved whether it is an anæsthetic or not, in the same way as in the case of chloroform, because no human subject ought to take it?—It has never been used or put before the profession in such a way that it could be used on the human subject as an anæsthetic, so far as I know. The way in which it was tried 40 years ago was to put a little of it under the skin of a rabbit and see the rabbit die in a minute or two.

1076. And you never saw it applied to the human subject?—No; I have never known it used for the human subject.

1077. We are told that the reason why it is recommended in experiments is not that it makes the animal insensible to pain, but that it makes the animal still and quiet. Do you know whether that is the case?—I should doubt very much its making the animal insensible. I do not know it of my own knowledge, but I have very strong ideas with reference to these experiments performed under anæsthesia as being far less valuable. I do not go in with that view, which is very prevalent, that these experiments may now be permitted because we have got anæsthesia to prevent the pain. The experiment is not of the smallest value during its performance. You cannot make a perfect experiment on the animal until it is in its normal condition.

1078. That does not imply that you do not think that the animal is made as insensible to pain as the human subject would be?—I fancy so. I do not think that there is much difference.

1079. What you mean is that if a man tries his experiment of course he hopes it will be a successful one; whereas you think that the anæsthetic may so derange the animal as to prevent its being successful?—It would be difficult for them to see what they want to see under anæsthesia, because the animal is no longer itself. An experiment on the human subject, for example, to whom you have given an anæsthetic, chloroform say, goes this length,—that the person is rendered insensible, and you may do any kind of painful thing to that individual for the time. That proves what I say. But further than that the anæsthetic has no other value, because when a person, having undergone an ordinary surgical operation recovers from it, then he suffers just the same in every respect as if he had not had chloroform at all during the performance of the operation.

1080. In the after suffering you mean?—In the after suffering; and there I think there is a great weakness on the part of those who try to make it appear that vivisection of the lower animals may now be more readily done than it could be before,

Sir W. Fergusson, Bart., F.R.S.

12 July 1875.

because an experiment at the time of an animal being insensible is really of little or no value.

1081. Several of the witnesses before us have said that they think that anæsthetics ought to be employed wherever they could, and that the animal should be killed before it woke up to sensation. What have you to say to that?—I myself cannot understand these experiments as a surgeon; I do not see what value they can be of at all.

1082. You think that the fact that the animal was under at least the temporary influence of a powerful poison would throw great doubt upon the whole nature of the experiment?—Upon the value of the experiment I think it would. I have no doubt whatever that in the case of a rabbit or a dog you could make it so insensible that you might cut out all its bowels, and the animal would never express pain by any mental or physical indication. Then of course you know what would happen after that.

1083. As far as regards an experiment for merely enabling an operator to do an operation, that is to say, for a surgeon, you would say that such an experiment would be of very little use, or that it would be very doubtful whether it would be of use?—I think this is an instance which I would put at once to any man who is trying an experiment of that kind intended to be applied to the human subject, because we have had more experiments performed on the human subject than have ever been performed on the lower animals during anæsthesia.

1084. But that objection of yours to that kind of experiments would hardly apply, would it, to experiments that were physiological, such as the discovery of the circulation of the blood, because these are experiments to see the actual process within the human body?—That I think is right enough; but I do not see that it is applicable; moreover that is a wrought out subject.

1085. But am I right in rather gathering this from your evidence, that although you would not say that no future experiments of this kind might be useful, or even under certain circumstances necessary, yet you attach less value to them than many other members of your profession, for two reasons; first, because the actual experiment itself puts the animal into an abnormal condition; secondly, that anæsthetics when used, would in addition put the animal into an abnormal condition?—I have no strong ideas about the experiment itself apart from anæsthesia, though in some instances I believe dogs laid hold of suddenly and violently and pinned down on a board, get into such a violent and excited state that you have not the animal in its normal condition.

1086. (*Mr. Erichsen.*) In reference to a remark that you have just made, I will ask you a question, because it is novel to me. Is it the case that dogs are ever "pinned" to boards, or that animals are crucified, as you said in another part of your evidence?—I have not myself seen it, but I have heard of it frequently, and I have had brought under my notice in the last nine months the case of two dogs being strapped to boards (I meant pinned to them in that sense) at Norwich, and a surgeon went up and cut the straps so as to let the creatures have some kind of relief. Let me also draw your attention to this,—you know that frogs are not strapped; they are pinned and tied; pinned more frequently than in any other way.

1087. With regard to surgical experiments, you have had immense experience, as we all know, not only in surgery itself, but also in the education of young surgeons, and in watching the process of many surgeons through life. Is it your experience or not that surgeons perform operations upon living animals with the view of accustoming themselves to operations, so as to acquire dexterity in operations on the human subject?—It is not my experience. I have heard it said that it might be done.

1088. But it is not your experience that it is so done in this country?—Certainly not.

1089. I gather from you that it is not the habit of surgeons to practise vivisection for the purpose of acquiring dexterity upon human beings?—Certainly not in this country.

1090. And that it would be useless to do so, because the condition of the tissues is very different?—Yes; the surroundings are so very different that I should place no confidence in any man who acquired additional experience in that way.

1091. A great many of the most eminent surgeons in this country, Sir Charles Bell, Sir Astley Cooper, Sir Benjamin Brodie, Mr. Travers, Mr. Lawrence, and others, have all performed experiments of various kinds upon animals; these have been to elucidate a certain definite point, and in the hope of adding something or other to the general stock of human knowledge?—They have also been performed by gentlemen, such as these, to aid in the development of special views of their own, and, so far as I have been able to judge, very legitimately.

1092. You stated, I think, that operations in surgery were not usually first of all performed upon animals, and then upon the human subject?—Yes; I have a very strong impression to that effect. I have thought over it again and again, and have not been able to come to a conclusion in my own mind that there is any single operation in surgery which has been initiated by the performance of something like it on the lower animals.

1093. The operations that have been performed on the lower animals, with a view of elucidating similar procedures upon the human subject, have all been performed after those operations had been done on the human subject?—Invariably. Whatever has been done after is a matter of curiosity.

1094. We are told that some of these experiments have thrown great light upon practical surgery, as, for instance, Mr. Jones' experiments upon the kind of ligature to use upon the arteries; that before his time John Hunter used broad ligatures, and that bad results followed the use of those ligatures, and that the experiments performed by Mr. Jones threw great light upon the proper sort of ligature to use, and were consequently of use to surgeons. What is your view as to that?—Jones' experiments were of considerable value to surgery at that particular time; but they have all been done again and again.

1095. And it would not be proper to repeat them?—Certainly not.

1096. That is a past matter; but at the time they were of great service to surgery?—Up to this day, I may say with regard to that point, practical surgeons seem to have as much difference of opinion as to the best kind of ligature as they had in Jones's day.

1097. Experiments have been made of late years on that very point by Mr. Lister of Edinburgh?—Yes, and by many others.

1098. (*Mr. Forster.*) Experiments on animals or on the human subject do you mean?—On animals and on the human subject; experiments are going on on the human subject daily just now; but these are rational experiments, quite legitimate.

1099. (*Mr. Erichsen.*) Experiments on the human subject, that is to say, after the operation; one surgeon uses one kind of ligature and another another?—Yes; it is the object of the experiments to ascertain what is best. But in saying that I do not mean to say that it is a reckless operation as to human life.

1100. I am not at this moment speaking of the indirect influence that experimentation on the lower animals has on the progress of surgery, but we have been told that certain observations, such as those which are made in what may be termed pathological experimentation, the production of inflammation for instance in the web of a frog's foot, and so forth, have had a very direct bearing (and no doubt they have) upon the progress of medical science. Have such experiments, in your opinion had any direct bearing upon the progress of surgical practice?—Well; I do not think it. I am as familiar as most people with these

Sir
W. Fergusson
Bart., F.R.S.

12 July 1875.

experiments, and I cannot say that I have been much impressed with the value of them.

1101. Has your own practice been very much influenced in any way whatever by what has been observed in this way in the lower animals; or has it been the result of your own clinical and pathological observation on the human subject?—Chiefly the latter; and since I have been indoctrinated with the usual views that are held in this country, I cannot say that I have had my mind opened up by experiments to any increase of knowledge on this subject.

1102. I suppose we may say this, that medicine is based upon physiological, but also upon clinical observation and pathology?—Yes.

1103. And in your opinion is clinical observation and pathological observation of more service to practical surgery than experimental physiology?—Yes; there is a precision in the one, whilst the other is largely theoretical.

1104. (*Mr. Hutton.*) Have you seen anything of the experiments for the transfusion of blood to which Sir James Paget referred in his evidence?—I think I may have seen once or twice the transfusion of blood from one human being to another, and I have known it in my experience again and again.

1105. Can you say whether the experiments on animals on that subject were in your opinion essential to the determining of the proper conditions for that transfusion?—I do not think they would be of the smallest practical value.

1106. You were a witness, were you not, of that experiment at Norwich which has been alluded to?—No, I am happy to say I was not; I was a witness in the trial.

1107. But in your opinion the attempt to determine the effect of absinthe and alcohol on the stomach by transfusing it into the veins of an animal was a perfectly useless experiment? — I think it was grounded upon incorrect views altogether. There is no strict analogy between the two, particularly when you want to put that analogy in association with a similar thing in the human body.

1108. And did I rightly understand you to say that Mr. Jones' experiments on the ligatures had not determined the question at all of the kind of ligature best suited for the arteries?—That is so; the controversy has been going on ever since, and variety of opinion still exists.

1109. Experiments on the human body are much more efficient for the purpose than experiments on the arteries of animals?—The ordinary operations, I would hardly call them experiments, are much more efficient; all such experiments have been founded on reason, and without any risk to the human being.

1110. Do you know anything of this handbook of Dr. Sanderson's?—I have heard a good deal about it, but I have purposely rather avoided it.

1111. You cannot give any opinion on the experiments described in it?—I have heard something about them; I fancy a large number of them are such as ought not to be sanctioned.

1112. (*Sir John Karslake.*) Would you let me know what are the grounds upon which you state the opinion that there is a great deal of reckless practice of vivisection going on at the present time?—I hear young men who are pupils, or have recently been pupils, speaking of what they have seen in the theatres, lecture rooms, and laboratories of those who profess to teach physiology.

1113. Could you point out to the Commission particular theatres or lecture rooms or laboratories in which you have heard that these practices prevail? —I could not be precise.

1114. Could you give us some clue by which we could get evidence for the purpose of ascertaining to what extent they prevail?—I can only do it in very general terms. I should recommend inquiries to be made at any of the physiological institutions in London and elsewhere.

1115. It is from what you have heard of what goes on at those theatres and laboratories that you have formed the opinion that there is a great deal of reckless practice of vivisection prevalent at the present time?—Yes; and I might have seen it in the papers too. In some of the Edinburgh papers recently there has been a letter from "A Citizen of Edinburgh," in which he questions the propriety of the system by which, when they are building a new university in Edinburgh, it should appear conspicuously that very careful provisions are being made for the lower animals that are to be kept in the institution for the purpose of performing experiments upon them. I think that is proof enough to show the estimation in which in certain quarters that style of practice is held.

1116. My question was rather pointed to the prevalence of the practice. and the sources from which we could ascertain whether it does prevail, and if so, to what extent?—I think the best authority that I can refer you to is the best and largest of the teaching institutions in London.

1117. (*Chairman.*) Your opinion is that the value of these experiments has been altogether exaggerated? —I do hold that opinion.

1118. But that if in the hands of the principal scientific men in this country, public opinion would be a sufficient check upon them?—Yes, that is my impression.

1119. And that the notion of being generally reputed to be very indifferent to suffering would be such as to prevent any of them continuing so or becoming so, even if they would otherwise have been disposed to become so?—Yes; I think public opinion would have a large influence upon the practices of such men.

1120. For that purpose it would be necessary, would it not, that something should be known about the proceedings that were going on in the different theatres and lecture rooms?—It would certainly be beneficial to your investigation that you should know that.

1121. But for the influence of public opinion upon scientific men, it would be necessary that public opinion should have something to form itself upon, would it not?—Yes.

1122. That is to say, unless the public knows what is going on, it can neither form nor express any opinion upon it?—Quite so.

1123. And your opinion, as I understood you, is that at this very moment there is a great deal going on in this town which, if the public did know, would excite them very much?—That is my impression from what I hear.

1124. And public opinion is in the present state of the law and practice of the country quite unable to bring itself to bear upon it?—Yes.

1125. Something therefore must be done in order to enable that public opinion to produce the effect that you speak of, must it not?—Possibly you gentlemen might bring before you some of the most intelligent of, say the young members of the profession, or the senior students in the profession, who have recently been attending lectures and demonstrations on physiology, and from them perhaps you would get the information.

1126. But I want to draw your attention to a different point. You have said that something requires to be done to check what you consider an amount of cruelty now going on?—Yes.

1127. But when pressed upon the subject as to the particular mode of doing that, you expressed a hope that public opinion would have a sufficient influence to bring about that result?—Yes.

1128. Then what I have pointed out to you is that under the present state of our law and of our practice these things appear to be going on, and yet public opinion appears to have no opportunity of operating because it does not know what is going on?—Yes,

Sir W. Fergusson, Bart., F.R.S.

12 July 1875.

1129. It will therefore, according to that view, be a consideration for this Commission, whether they should not recommend some change in the law and practice, by which everybody who does these things shall hereafter be subject to some influence of public opinion; is not that so?—Yes.

1130. That would point to some change in the law?—At all events, to an expression of opinion from some of the highest sources in the kingdom.

1131. But an expression of opinion which should not be brought to bear upon the practice of a person who is permitted to continue the practice without the knowledge of the public would be inoperative, would it not?—We have already in some degree referred to that. First of all I would suggest that if you gentlemen were to have information sufficient to convince you that such practices are going on to an extent that you do not think should be permitted, it would be for you to recommend to the Government to either say or do something on the subject. Then I think I would say as to the next part of your question that in the present state of the law we have the Society for the Suppression of Cruelty to Animals keeping a constant watch upon such matters, and a person amenable to the law at this present time for cruelty to animals would be still more likely, I think, to be put in the right course, or to have his practices suppressed altogether, if it were done under stronger sanction than there is at this present time. There is the common law at this present time, but we should have some additional expression indicating that Government could not tolerate this sort of thing in this country.

1132. At the present moment there is, according to your belief, much going on somehow or other which ought not to go on?—That is my impression.

1133. And that probably the law and the practice, as it stands at present, is not sufficient to prevent it?—It does not reach it at the present time.

1134. And that which you would recommend would be, I suppose, that some change in our law and practice should be made which would enable us to reach it?—Quite so.

1135. And then, so far as the most eminent scientific men are concerned, you think that after that had been done, public opinion would have sufficient influence with them?—The fear of an unfavourable public opinion, I think, would have great influence with them.

1136. Then with regard to other persons than those eminent scientific people, it might, perhaps, be necessary for some severer measures to be taken with regard to them, might it not?—Yes; if there was excessive cruelty or an excessive want of common humanity.

1137. Supposing a comparatively ignorant person, from whose experiments no real good could reasonably be expected, were nevertheless to practice such experiments; do not you think that something stronger than public opinion might be brought to bear upon him?—I think there would be some difficulty in applying that to people in the position of quacks and bone-setters, and so forth; because you might arouse in the mind of the public the feeling that the man was a persecuted man, that the whole profession had gone against him, and you might make rather a martyr of him than otherwise, and probably an elevated martyr.

1138. In fact, you would suggest that if the Commission did recommend any further proceedings, they should take care not to exceed the limits of public opinion, not to go beyond what public opinion might be expected to support?—Yes. I think when you are referring to that subject, I may say that it has struck me that it would be well, with a view to what may be the result of this investigation which you are engaged in, if the attention of the governors of medical schools were called more forcibly to the subject than at this present time; that there might be certain governors in each school who should take an interest in the matter, and see that there was no unnecessary cruelty in a part of the institution where it is admitted generally that there must be a certain amount of cruelty for special purposes.

1139. But that is limited to the great hospitals and scientific schools, is it not?—Yes; it would be limited to them; but I do not think there is much of this that goes on irrespectively of these schools. I do not think that there is much amateur physiology going on in this country.

1140. But if there was, it would be still more necessary, would it not, to provide a remedy in that case?—Yes; if that was ascertained, it would be a very important thing.

1141. (*Mr. Forster.*) I think you said that you think what does go on that ought not to go on is mainly at the large institutions?—So far as I can make out. I believe that here and there there are outsiders, so to say (I speak of them with respect), who are not actually in these institutions; they are zealous and talented men, and take opportunities of their own where they can; and I think it would be a pity to restrain even these men, so long as it was seen that they were under a wholesome influence.

1142. Has it ever occurred to you whether, as regards these large institutions, it might not be well to put them under the obligation to make a public report of the experiments that they were performing?—That has occurred to me. It might be a very good rule to make.

1143. Take for instance what is going on now; we hear different accounts, and it is very difficult to know accurately what is going on, and therefore it is very difficult for public opinion in any reasonable manner to operate upon them; but supposing they were under an obligation to declare what they had done, and why they had done it, then public opinion could form, could it not, a reasonable judgment?—I think that in legislation on the subject it would be a very important thing to have some view of that kind developed. It had a very wholesome effect on the conduct of dissecting rooms, for instance. Now there cannot be a subject in a dissecting room without there being a proper account of it, where it has come from, how long it has been there, and so forth.

1144. At the present moment they are compelled to keep an account of dead human bodies?—Yes; and if there is a large piece of a body lying there that cannot be accounted for, the individual that has that piece, the professor of anatomy, is immediately amenable to the law, and the law is very stringent; he would have his license taken from him, and his school, so far as the teaching of anatomy was concerned, would be put an end to. There is a very wholesome regulation of the practice with reference to that matter.

1145. And in the same manner, I suppose, it would be possible to say that a report must be made day by day of any experiments on a living animal, and why it was done?—At certain dates. Day by day would be perhaps too much officiousness; but I have thought in my own mind that it would be quite possible that you should have an inspector of these experiments, just as they have an inspector of anatomy; and that just as the common law enables the authorities to send detectives in certain directions to ascertain who may be in certain houses, so they should be able to send men who might say: "I should like to see the "number of dogs and rabbits or cats about this "place." I think that would have a very wholesome effect.

1146. (*Chairman.*) There was a great excitement about anatomy, we are told, (and many of us are old enough to remember it,) when the law was in its old state?—Yes.

1147. That excitement was entirely put down by the changes which have since been made, and there is no public complaint any more on the subject. Do you think that something analogous to that might be

Sir W. Fergusson, Bart., F.R.S.

12 July 1875.

adopted if there should be reason to believe that things are done in this matter which would not be satisfactory to the public if they knew of them?—Yes, I think it would be a very wholesome thing to do, if this Commission were satisfied that these practices are carried to an exorbitant extent.

1148. In other words, if they were satisfied that there was sufficient occasion?—Yes.

The witness withdrew.

Adjourned to Wednesday next, at 12 o'clock.

Wednesday, 14th July 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. W. E. FORSTER.
The Right Hon. Sir JOHN KARSLAKE.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

Mr. N. BAKER, Secretary.

ALFRED SWAINE TAYLOR, M.D., F.R.S., called in and examined.

A. S. Taylor, M.D., F.R.S.

14 July 1875.

1148. (*Chairman.*) You are a Fellow of the Royal College of Physicians and of the Royal Society?—I am.

1149. What is your exact position at Guy's Hospital?—Lecturer on medical jurisprudence and toxicology, an office which I have occupied for 44 years.

1150. You are also the author of the works on Poisons and on Medical jurisprudence so constantly resorted to when questions of that nature occupy the attention of the courts of law?—Yes.

1151. During the time you have mentioned what has been your experience with regard to experiments on living animals?—It has been of a limited kind. I have performed a few occasionally.

1152. Do you mean a few experiments with the knife; or that the whole number of your experiments, including those with poisons, has been a limited one?—In some cases the knife has been used to produce a slight wound for the introduction of poison; that has been the only use of the knife.

1153. And that is not of a painful character?—Not of a painful kind; a very slight wound is sufficient for that purpose.

1154. Have you experimented largely in toxicology?—Yes, I have in reference to poisons.

1155. I think that you were much employed about the trial of William Palmer?—Yes, and indeed I have been employed for the Government for more than 20 years on all great cases, including those of Palmer, Smethurst, and many others that have been tried,—in Palmer's case especially.

1156. Would you relate to us, if you please, your experience in Palmer's case?—In Palmer's case it was necessary to perform some experiments on living animals, as so many conflicting results were reported to have been obtained by experiments performed by witnesses for the defence. Dr. Rees and I on that occasion found it necessary to experiment on, I think, six rabbits.

1157. And in the result, the evidence which you gave led to Palmer's conviction?—It did. It showed that the power of discovering the poison depended on the amount given to the animal, and the time that it lived after taking it; whereas it was said, I may casually remark, that if an animal or a man died from poison, it must always be found in the body. Our object was to see whether we could kill an animal without necessarily finding it. We satisfied ourselves that one of these rabbits at any rate died from a poison which had been introduced by absorption, and that no trace of it could be detected in any way, the quantity which killed it was so small.

1158. Is it your opinion that experiments are resorted to in such cases to a greater extent than is necessary?—I think so; and in that case they were particularly.

1159. Have you tried experiments to determine the influence of the poison of the Cobra di Capello?—Yes, those were the last experiments I performed. They involved some very curious points of physiology. I had a quantity of the dry poison of the Cobra di Capello given to me.

1160. Was that for a question of jurisprudence?—Rather physiology; because serpent poison would hardly come in except in the general way of showing death by absorption. It was therefore rather a physiological than a medico-legal point. I may state that the poison was collected from a Cobra in 1861, and I received it in 1873, 12 years afterwards; it had been kept in a dry state in a tube; and I used a small quantity of it to test the question,—whether the poison remained for that long period unchanged. I found that it did; that it destroyed a rabbit in a quarter of an hour when introduced by a wound. Then there was another important question. It had been long said that the serpent poison would only operate through a wound; that had been recently placed in a little doubt by some experiments; and Dr. Pavy and I determined to test it. We made a dog swallow two grains of the Cobra poison after he had been kept fasting for about 25 or 30 hours (that was necessary to promote absorption); but the animal manifested no symptoms of injury at all; he perfectly recovered, indeed there was no effect; so we let him go, and gave him a good meal; and that clearly satisfied us that this dreadful poison operates chiefly by absorption through a wound, and not through the stomach.

1161. Had it any bearing on any particular case of jurisprudence?—No, not at all; it was a mere point with regard to physiology in reference to the action of serpent poison, and it was done in order to try and settle what had been a contested question.

1162. Can you give us, from your long experience, some instances in which your experiments have had an important bearing upon recent cases of jurisprudence?—Yes. The case to which I am about to allude occurred in Suffolk about 12 or 14 years ago. A woman was charged with poisoning her step child, a little girl; she had applied to the head an ointment of white precipitate mixed with arsenic, to cure the ringworm; the child died from the effects of the poison, and it was charged that the woman had treated her cruelly, that she had deliberately caused her death; and this seemed to be borne out by the fact, that although she said she had applied the poison to the head, it was discovered in the stomach. The experiments performed by Dr. Pavy and myself were these;—to see whether, when poison was introduced into the blood by a wound, or absorbed in any way and circulated, any portion of the poison might find its way into the stomach. I may say that the quantity which I found in this child's stomach was exceedingly small; it was in a dissolved state mixed with the general fluids of the mucous membrane, and there was no appearance of food. Upon performing experiments on rabbits and dogs

A. S. Taylor, M.D., F.R.S.

14 July 1875.

Dr. Pavy and I found that arsenic injected into the blood or through a wound, if the animal lived a few hours, was in part eliminated by the mucous fluids of the stomach. In short, it goes out by the urine, and by all the fluids of the body, and the stomach itself becomes an eliminating medium. The quantity I found was so small that I was able to say that I believed it to be simply the result of elimination from absorbed poison. This inference was borne out by other circumstances. There was no time at which symptoms of arsenic as a poison acting through the stomach had appeared; the symptoms were wholly different; none appeared for two days; and this satisfied my mind that it had not been given in the usual way by the stomach. The child died from the effects of the poison clearly. The jury were satisfied with the evidence given upon my statement, that the discovery in the stomach did not prove necessarily the administration by the mouth, the quantity found being so small that it was consistent with elimination by the fluids of the body. It was rather a novelty to demonstrate by experiment that from the outside of the body, the poison could be carried into the interior of the stomach. That was the object of these experiments, and I think the results had the effect of preventing a verdict of wilful murder from being returned against the woman. The coroner's jury returned a verdict of "Died from poison, but the result of accident;" so it went no further than the coroner's inquest. Up to this time I believe it had not been clearly proved by science that a poison could find its way from the skin to the stomach.

1163. You justify the performing in that case of experiments upon dogs or rabbits by the result which showed the action of the poison of arsenic in this particular case, and saved the woman from being the subject of a criminal trial?—Yes.

1164. Now do you think that there are many cases in which experiments of this nature are performed with benefit to mankind?—Yes, I think there are.

1165. Do you think that there are more performed than there is much necessity for?—I do; and I would say that it has become rather a custom in notorious cases of poisoning, cases which attract great public attention, such as Palmer's and Smethurst's, for many persons to experiment very unnecessarily upon animals for the purpose of working up the prosecution or defence. I have mentioned in a note to your Lordship that in the Palmer case "one medical man" boasted of having operated upon and destroyed 60 animals.

1166. (*Mr. Forster.*) Did he appear as a witness?—He appeared as a witness for the defence; a large number of animals were thus destroyed on the part of the defence.

1167. (*Sir John Karslake.*) Would you add to that what the reasons which he gave for his experiments on these animals were?—I can hardly explain; for the results at which he arrived were only what we knew before, that is that animals might be destroyed very rapidly by strychnia; but the greater number of the experiments, according to my recollection, seem to have been performed by him in order to determine the power of discovering this poison in all cases after death. That was the point. You will remember that in Palmer's case the evidence for the prosecution was greatly interfered with by the mode in which the viscera were handled after being taken from the body. The point dwelt upon for the defence was that poison was not found in the contents of the stomach. But it was not properly made known to the public that Palmer himself was present at the inspection of the body; that the stomach was cut open and the contents, with all the fœcal matter of the intestines and other viscera were thrown into one jar; and then as the poison was believed to have been given in pills, not in powder, it placed the greatest difficulties in the way of its detection; because without examining all the animal matter we should have found nothing—we found nothing in the stomach to account for death.

1168. (*Chairman.*) You think that a limited number of experiments was necessary, but that a very unnecessary number were resorted to?—I think so on all sides. There were a great number of witnesses who appeared on the occasion for the defence, and they seemed to rest their case greatly upon the number of experiments, and indeed they put it that what Dr. Rees and myself did, namely, in four or six experiments only, were not to be relied upon. The late Mr. Serjeant Shee dwelt upon this as a strong argument, that we had worked so little that we really had no *locus standi* there to put ourselves forward to give an opinion—we were put down actually by the number of experiments performed on the other side. So far you see that experiments upon animals may be carried to an unnecessary extent for the purpose of a defence, for after all, a hundred experiments in which the poison was found, would not overthrow a few in which it could not be found, the results varying according to the circumstances.

1169. Your opinion is that, when once a thing has been proved by a sufficient experiment, further resort to experiments in that case is purposeless cruelty?—I think it is.

1170. Do you think that, speaking of toxicological experiments, when performed even by men of great names in science, they are always necessary and really conducive to scientific results?—They are not always so. They may have an intention of working out some problem in their own minds; but as for being of general use in science, they certainly are not so; a number of experiments in fact are uselessly performed.

1171. Would you give us an illustration?—I would say that was the case chiefly among the French authorities, and, without perhaps naming individuals, I may say that a very eminent toxicologist was in the habit of experimenting upon dogs on a very large scale indeed—and after giving the poisons (nearly every poison in the list that we know of), to the animals by the mouth he cut into the neck to tie the œsophagus (the gullet), to prevent the animal vomiting; and of course that must have caused great pain and suffering, and it also prevented the efforts of nature to get rid of the poison, and as the same time it defeated the object which a toxicologist ought to have in view, because it placed the animal in an unnatural condition; for one could not fairly judge from the symptoms what the effects would be from that particular poison. For that reason in my work on Toxicology I have not been able to make any use of the hundreds of these experiments which this French physician performed; I have only been able to make use of those observations that were made on human beings, where the poison was allowed to act in the usual way without interference. The application of a ligature to the gullet was attended with great pain and suffering, and defeated the very object for which he undertook it. He wanted to prevent vomiting, and in doing that he altered, of course, all the circumstances which we should study in regard to a human being. Others have worked since that time on dogs, but I believe not in quite so cruel a fashion. Another eminent French toxicologist now living, has operated, I know chiefly, on small birds, pigeons, and sparrows, without resorting to experiments of this kind.

1172. Are those kinds of experiments really conducive to scientific conclusions or not?—I can hardly say that they help us much, the results depend so much on the weight of the animal and the circulation of the blood, and so on; they allow us simply to say this, "Such a substance is a poison or not." The toxicologist has tried an experiment with the poison of serpents or the Cobra poison, and it has just allowed him to say "This destroys the life of a small animal," and that does not help us in medical jurisprudence. In fact, I have never quoted, in any evidence that I have given, the results of experiments upon such animals as frogs or birds.

1173. Now taking strychnine, does it follow that the action of strychnine upon all of the lower animals would be the same, or nearly the same, as on the human being?—Upon all those furnished with a spinal marrow it would.

A. S. Taylor, M.D., F.R.S.

14 July 1875.

1174. But upon others?—Upon the invertebrate it would not, that is upon such animals as the bots found in the stomach of horses, or the larvæ of insects. With regard to them, they are not provided with the requisite conditions; they have no spinal marrow, no medulla oblongata, and therefore the poison has not that organ to act upon. I have buried these animals in strychnia sufficient to destroy a human being, and they have crawled out of the poison. Of course we derive nothing but the curious information that it requires a certain organ to be affected by a certain poison. Strychnia is what is called a spinal poison, and animals destitute of a spinal marrow do not suffer from it in the same way as others.

1175. Then it requires a great deal of scientific knowledge to form a just opinion whether a particular experiment in toxicology will be of any use, or not?—Yes.

1176. Use for purposes I mean of application to the human subject?—Yes.

1177. Either in regard to medicine or to jurisprudence?—Yes.

1178. And you think that many experiments are resorted to which are evidently useless for those purposes from the beginning, and which inflict a great deal of unnecessary torture upon the animals that are subjected to them?—Yes, I do. I would apply that observation more to French experimenters than to English, judging from my own knowledge.

1179. When a scientific conclusion has already been firmly arrived at, do you think it justifiable to expose animals to torture merely for the purpose of demonstration?—I do not, and I have invariably acted upon this principle. For a long period of years I have had to go over every poison that destroys human life (I have only just finished the summer course now), and with regard to strychnia, the facts are now so well ascertained as to its operation, and there have been so many observations, not only on animals, but on the human subject, that there really is no point to be gained by poisoning an animal with strychnine; we gain nothing by it, and in my opinion it is a cruel experiment.

1180. Purposeless cruelty, you think?—Purposeless cruelty.

1181. Have anæsthetics made a great change, do you think, in the question referred to us?—Well, I am not aware myself of their having been used, I have only heard it, and do not know it from any direct personal knowledge; but there are many cases in which the use of them might interfere with the object of an experiment in toxicology, because we require something like an active nervous system to show us what the effects of a poison are, whether the brain is affected, or the spinal marrow, or the sympathetic nerve, or other parts, and this we could hardly know if we destroyed sensibility by another poison before beginning to apply the poison in question.

1182. Now, is it necessary for such a purpose as that that the experiment should be long protracted, I mean for the purpose of discovering the nature of the operation of that particular poison?—No.

1183. Then would not the consequence follow that the animal should be put out of its pain as quickly as possible?—You mean after the performance of the experiment; yes.

1184. Now, do you think that the most eminent men in this country would be as desirous as any other men to assist in remedying the evil of which you have spoken, if it exists in this country, namely, that of trying experiments which are in their nature severe and also useless, or trying repeated experiments merely for the purpose of illustrating points that have been already established?—I think that scientific men would have no objection to join in that view at all. I think the object of scientific men in England generally, as far as I have known, has been merely to obtain some actual benefit from the destruction of life, and that they have rather avoided destroying life where it has led to no useful conclusion. I believe that they would join in any Act which the Legislature might enforce in trying to put down the useless and purposeless extinction of animal life for any object.

1185. Has it at all occurred to you what direction any such measures might take if they should be resorted to?—I have thought of that, but there appear to me to be very great difficulties. First of all it would be necessary to draw a clear line about animals, as to what animals are to be exempted from experiment, except under precautions. Another point would be this: if it were alleged that an experiment had been performed cruelly and unnecessarily, I doubt whether any magistrate or any ordinary authority would be able to form a judgment in such a case, unless at least he were assisted by some one acquainted with the subject, and with the object of the performance of such an experiment. Therefore, I think that legislation, to be effectual, should in some way or other define the animals or the class of animals, and that a person or persons might be appointed to aid the opinion of a magistrate in deciding a case when the question was whether the experiment was necessary or not necessary; a magistrate himself could hardly undertake this duty.

1186. Some persons of great authority have drawn our attention to the analogy of the law with regard to anatomy; has that ever occurred to you?—I have thought of it; in fact from an observation made by your Lordship, it has struck me that this leaves certainly a path open, that if licenses were granted as under the Anatomical Act, it would be very easy to secure a power of control over the performance of experiments, so that no person should be permitted to perform them except with a license; and no person, of course, would be licensed except one of public position who had some direct object in the performing of those experiments. A great deal must be left to the discretion and feeling of scientific men as to their performance. I believe that the general desire of scientific men in this country (I am speaking from my conversations with those who have had to do with poison) is really not to destroy life if it can by any possibility be avoided.

1187. You think it is a sentiment of humanity?—Yes; and the only exceptional instances have been in some great trial, where perhaps a man has been desirous of bringing himself forward, or trying a new thing merely for the sake of a little notoriety in some instances. This has been the only exception which I have known in which they have departed from the usual course.

1188. Were you at all aware what passed at Norwich, when a great deal of attention was drawn to the subject?—I read in the Medical Journals what did pass about some injections that were made into a dog. To me they appeared to be of a most cruel kind, and to answer no purpose justifying the nature of the experiment. Of course there will be a difference of opinion always in such cases, and I think you will find generally that physiologists will maintain a right to experiment to any degree. Medical jurists, perhaps, will not go to that extreme; they will only resort to it in special cases in which some new question has to be answered, or some new point has to be ascertained, connected with the administration of the law. I think that as new poisons are continually being found, and improvements being made in toxicology, it would be impossible to shut out altogether the opportunity of experiments, and I might tell your Lordship, perhaps, that one of the most important points on which I should chiefly rely, in the event of chemistry failing to detect a poison in a dead body, would be the application to an animal of some part of the substance which was said to have caused death, in order to determine its nature. There is, for instance, the Calabar bean, and some other poisons which are coming into medicinal use, and may therefore fall into the hands of those disposed to perpetrate crime. The Calabar bean is a powerful poison, paralysing the heart and destroying life. We have no chemical means whatever of discovering it; but it is found on giving an extract of it to vertebrate animals that it operates by

A. S. Taylor, M.D., F.R.S.

14 July 1875.

suppressing the action of the heart, just as it does in the human being.

1189. (*Mr. Forster.*) As regards anæsthetics, many of the surgical and medical witnesses that we have had have approved of the suggestion that they should be used whenever possible in physiological experiments; but I suppose they would completely frustrate your experiments?—They would in toxicology. In regard to operations, I have no doubt about the propriety of their use.

1190. But in regard to toxicology, you could not try the influence of one poison while at the same time administering another poison, which an anæsthetic is?—No; we could not rely upon the results.

1191. You have studied poisons; now we have had a great deal of difficulty in finding out what is the real nature and effect of the curare poison, whether it is a poison which deprives the animal taking it of sensation or not?—I have not experimented much with that myself, but I believe that it operates on the nervous system, and that, given in what is called by hypodermic injection, it tends to act as a sedative on the nervous system.

1192. There are two theories about it, one that it does that, and the other that it merely stops the muscular action, and that therefore the animal may appear quiet and yet be suffering great agony?—I should doubt whether the muscles are not affected really through the nerves. I should be disposed to believe that the nerves are the first to be affected; but it depends on whether you use the curare extract or the alkaloid called curarina. I believe there is not a grain of the alkaloid in this country. I have only the curare extract, and that is a kind of preparation made by the American Indians, we do not know exactly how, and we are not quite sure that it is always made in exactly the same way.

1193. It is what they poison their arrows with, is it not?—Yes. It seems to act rapidly on the muscular system; the animal drops dead after running some distance; but I believe its real operation is on the nervous system.

1194. I suppose there is no case on record of any man having been poisoned by a poisoned arrow and recovered?—No, I have never heard of any.

1195. You state that for the defence in murder cases sometimes there are a great number of experiments tried?—Yes, in cases which excite great public interest that is so.

1196. I think you stated that you are of opinion also that they are needless in their extent?—I think they are.

1197. But would it not be very difficult to limit by law the power of a man tried for murder to accumulate evidence on his behalf?—Certainly it would; but I think that an accused person does not improve his position with regard to scientific evidence by the destruction of so many animals. Now, to take the case of one witness who gave evidence for the defence in Palmer's case, the destruction of 60 animals, looking at his conclusions, was really quite unnecessary; it was merely an effort to overwhelm the evidence for the prosecution by the number of experiments.

1198. I suppose that the counsel for the defence used a number of experiments showing a certain result as an argument?—He used the totality; he said, "Sixty experiments against four." But one experiment may be better than 20, according to the mode in which it is performed.

1199. Do you think that that argument could be of any real service?—No, I do not think it influenced the jury; but it did so happen in that remarkable case that the foreman of the jury was a man thoroughly acquainted with the action of strychnine on animals.

1200. Do you remember that curious case of Tawell?—Yes, I was consulted in that.

1201. Were there any experiments in that case?—Not many; that was by prussic acid, and all the facts connected with that are pretty well known.

1202. What animal do you imagine would experience the effects of a poison most like a human being?—A dog. I might mention to you that the doses of poisons for a middle sized dog are very similar to those which will act upon a human being; so that a middle sized dog comes the nearest to a human being; the symptoms of suffering and the whole course of the proceeding are really very much the same.

1203. Do you think that these experiments are useful, not merely for legal purposes, but also for discovering antidotes to poisons?—I think they are.

1204. Do you know of any cases in which an antidote has been discovered by the help of experiments—I have known cases in which it has been said that the hypodermic injections of certain antagonistic poisons have had a good effect; but I have not myself experimented in that way by the injection of a poison beneath the skin. Now, in the case of strychnia, curare has been employed among other things. It has been said that that administered to animals or injected beneath the skin has had the effect of counteracting the excessive stimulus which strychina produces. But unless these poisons are used in proper proportions the animal is likely to die. I do not put much faith in them, and I do not know that we have yet learnt anything, so far as treatment is concerned, from our experiments with them on animals. With reference to prussic acid, an experiment which did not involve any wounding of the animal, the placing of a dog or cat under a tap of cold water has roused it; and that has been found a good remedy in human beings, cold affusion; this did not involve suffering.

1205. Sir James Paget illustrated what he conceived to be the necessity of experiments in some cases, by the endeavours to find out a cure for snake bites, by which it is stated that 20,000 are killed every year in India. Do you imagine that experiments are likely to do much good for that purpose?—No, I do not. I have read them all with great care. Ammonia has been recommended by Dr. Halford in Australia; but this has proved utterly inefficient when the experiments have been fairly performed; and, in truth, if you consider for a moment the mode of death from poison, you will see how difficult it is for any antidote by injection to operate. The poison rapidly gets into the blood, when in the blood it alters this fluid; and unless the remedy proposed enters into the blood quite as quickly, and very soon after the poison has entered, no good can be done. There may be some slowly operating poisons; but with regard to serpent poison, when it once enters the blood, the effect is most extraordinary, the rapidity of death is very great indeed.

1206. Not many murders are committed in these times by slowly operating poisons I suppose?—No, not many. It has unfortunately transpired that some members of the medical profession, or men connected with the medical profession, have thus made use of their knowledge in an improper way where chronic poisoning has been the cause of death. The public in general know nothing about what we call chronic poisoning, the administering of small quantities at intervals. The only cases that I happen to remember were the case of Palmer who poisoned his wife, and Smethurst, and Pritchard, and two or three more who showed in the use of poisons a kind of medical knowledge which we have not to contend with in the public in general.

1207. The poisoner, to succeed in such cases must have constant access and also knowledge?—Yes; and there the public are so far safe. The general effect in all cases of criminal poisoning to my mind is this: the poisoner does too much, he gives too large a dose, and by that, the crime is detected.

1208. (*Sir John Karslake.*) Do you consider that there are many cases in which it is inexpedient to give to the world, generally through publications, the history of the operation of a particular poison?—I think it is so with regard to those which we are unable to detect by chemistry.

1209. If those experiments which have been made and which have established the effect of a particular poison, are not generally circulated among the members of the medical profession, does not that lead

A. S. Taylor, M.D., F.R.S.

14 July 1875.

to further experiments being made by those who have not the means of that knowledge for the purpose of establishing facts which are already established, if they were only known?—It would be so.

1210. Is not that very objectionable?—It would be objectionable; but at the same time we must steer between two difficulties, on the one hand of not making these matters too public, but at the same time giving enough to inform professional men. I have endeavoured to do that in a work on Poisons lately published, that is to say, to give to professional men knowledge without giving knowledge to the public.

1211. You give the hint without giving the full details?—I doubt whether it would even amount to a hint.

1212. I have understood from one of the gentlemen who have been before us here that any discoveries that are made are generally published to the profession almost as soon as they are made, and that is a strong reason against repeating experiments when the facts have been thoroughly well established?—No doubt in the medical journals we find all that is new brought forward; but I do not know that this would limit or affect much the number of experiments.

1213. I think you have said to Mr. Forster that you would not propose to limit by legislation the power of medical and scientific men to ascertain facts for the purpose of establishing a defence in a serious case like a case of murder?—I would not; and indeed, for the improvement of physiological science, there may be a great many things justifiable; the only thing is not to multiply these cases and perform experiments unnecessarily, but to have a certain definite object in view.

1214. That which would be a very great argument to adduce before a jury might be considered insufficient by scientific men?—Yes.

1215. It might be a strong argument to a jury that in 50 cases in which an experiment had been tried no particular result had occurred to oppose to evidence that in one particular case that result had occurred? Yes; they would however be apt to be influenced by the number of the experiments.

1216. And by the argument that in the one case the experiment was not a satisfactory one, or that the experiment was not accurate?—Yes.

1217. Have the cases been numerous in which you have attempted to ascertain by experiments the difference in the size of the corpuscles between the blood of animals and the blood of human beings; the quantity of blood you have to take from the living animals for that purpose is very small, is it not?—Yes, the slightest wound will give enough.

1218. With regard to strychnine I think in some of the evidence already before us it has been said that it is important that medical practitioners, when they are students, should see the operation of strychnine upon animals to see how it causes death. Is that your opinion?—I really do not consider it absolutely necessary.

1219. I do not put it as high as "absolutely necessary," but that it was considered expedient; is that your view?—No, I do not consider it to be so. If I had thought so I should have performed such experiments in my own class; but from having seen the results so frequently myself I think I have the power of describing to a class the symptoms so accurately that they would know them. There is something very dreadful in the operation of strychnine upon an animal; no doubt it suffers agonising pain.

1220. But the knowledge of the operation of strychnine in this country is comparatively recent, is it not?—Chiefly since the trial of Palmer.

1221. Or since that of Mrs. Sergison Smith, about the year 1847 in Hampshire?—Yes; but as long ago as 1831, when we knew very little about it, there was a case of life insurance, where a man had by means of strychnine destroyed a lady whose life he had insured. There a very eminent medical man was deceived, and set the case down to tetanus, natural disease.

1222. In your judgment at the present day are the symptoms of poisoning by strychnine so well established that it is unnecessary to show students the operation itself, in order to enable them to see what the effect of strychnine is?—I think it quite unnecessary.

1223. (*Mr. Erichsen.*) I would pursue the question that has been put by Sir John Karslake a little further, and ask you whether you think it necessary or not to poison animals for the purpose of demonstration to classes of students, in order to exhibit the post mortem appearances presented say by the stomach and intestines?—I do not think it absolutely necessary. Of course it would be a kind of addition to their knowledge to have something beyond verbal description; but there is no ordinary poison, the effects of which we are not now well acquainted with, in regard to the appearances of the body. I have relied a great deal upon the minute descriptions which I have given, and in producing wax models of the stomachs of human beings, but I have not considered it necessary to perform the experiments.

1224. Coloured wax models and drawings are sufficient, you think?—Yes.

1225. And it is not necessary to kill animals for that purpose?—No.

1226. (*Mr. Forster.*) A great many of the medical men who are called in to give evidence are medical men of not much note in their profession. If an inquest, for example, is held in a country place you must take the best man you can find?—Yes.

1227. Would such a man, do you think, be able to form a judgment about questions like strychnia poison?—If he has had a proper education according to the present rules of our colleges he would be. On one or two occasions I have experimented before a class, showing the effects of the mineral acids upon animals, but I have not carried that out to any great extent. I believe from a general acquaintance with students, that they have received as much information from accurate description and the illustrations by models and drawings, as could possibly be gained by experiments on animals.

1228. (*Mr. Erichsen.*) And do you consider it necessary to poison an animal in order to analyse the contents of the stomach, and so to show the students the method of analysing the contents of the stomach of a poisoned man?—No; I have a number of stomachs of persons who have died of poison, and I use them in preference to any experiments on animals. Articles of food and other matters have even been sent to me from Sierra Leone for analysis where poison has been used. These are kept, and they are used for demonstration before the classes without resorting to the destruction of animals.

1229. And in the other department, that of medico-legal teaching, independent of the toxicological department, do you find it necessary to destroy animals?—I do not call to mind any case.

1230. For instance, in illustrating the effects of wounds and injuries, and so forth?—The only instance I have known has been not for showing the nature of wounds, but for the production of fresh blood from an animal.

1231. But a mere puncture will suffice for that?—Yes, very little indeed will suffice.

1232. You are connected with one of the largest schools of medicine in the country?—Yes.

1233. Is it the practice in that school to allow students to perform toxicological experiments?—Yes; there is a practical class and a laboratory on purpose. I have not that department now; that is in the hands of another gentleman. We divide our work now, and the students are exercised in the examination of poisons.

1234. Upon the living animal do you mean?—No, chemically. Sometimes, I believe, my successor has given arsenic to rabbits to show the mode of extraction from the living animal. I have always preferred to take human viscera, and, having had so many cases sent to me to examine, I have had a sufficient number of them for experiment and demonstration.

1235. In the large school with which you are connected are experiments upon living animals done by

A. S. Taylor, M.D., F.R.S.

14 July 1875.

students for toxicological purposes?—No; the only experiments I know of at Guy's Hospital are those chiefly conducted by Dr. Pavy; they are not performed by the students, but by the professors themselves, and for a special purpose.

1236. So that it would be wrong to say that there was anything like reckless or improper experimentation at the school of medicine with which you are connected?—I think it would. I make this remark generally for England, from what I know about toxicologists, and, seeing all the works published, I think that the experiments performed on animals are chiefly by the French and Germans.

1237. (*Mr. Hutton.*) You think then that there is no reckless experimenting in toxicology in England at all?—I have never heard of anything of the kind, with the exception of what I have already stated, namely, that in some great trials there has been a desire to overwhelm evidence given contrary to certain experiments by increasing the number of them.

1238. You rather expressed a doubt about urari, but you thought it was an anæsthetic?—I believe it operates as a sedative.

1239. Claude Bernard says that it acts upon the motor nerves, and not upon the sensory nerves?—I am aware that this has been said. I believe the differences are to be explained by the fact that what is sold as curare, the extract, is liable to variation.

1240. You are aware that this urari is very commonly used now in the physiological laboratories in England?—Yes.

1241. Which would be used, the thing which you think would destroy pain or the thing which would only paralyse the motor nerves?—I have not heard much of anæsthetics being used at all myself.

1242. (*Mr. Forster.*) Supposing that you were going to make an experiment upon a living animal which could be done successfully under an anæsthetic, would you use this curare as such anæsthetic?—No, I should not; I think curare is far too dangerous a preparation to use.

1243. And too doubtful as to whether it really prevents pain?—Yes.

1244. (*Mr. Hutton.*) I find that in the case of frogs, and often in the case of mammals, in this handbook of physiology before us, curare is frequently the poison used?—I have tried in every way within the last month or two to get the curarina, the alkaloid, and I have not found it possible to do so. I am told it is only made in small quantity for experiments performed by some German chemist. The alkaloid, no doubt, would destroy sensation—the other thing, the curare, might or might not; its effects are variable.

1245. (*Chairman.*) That which you are sure would, is so rare that it can scarcely be obtained?—Yes.

1246. And as to that which is ordinarily used there is no security that it does?—No; and by giving it in any case you place the life of the animal in great jeopardy.

1247. (*Mr. Forster.*) And that alkaloid, curarina, would almost certainly kill?—Yes; the medical and scientific evidence about this substance is too conflicting to allow of its general use—chloroform or ether in vapour would be comparatively safe in preference to it.

1248. (*Mr. Hutton.*) With respect to the remark that it would be very dangerous to limit the power of private people to make these experiments in cases where justice is in question, do not you think that if a certain number of licensed laboratories were distributed throughout the country, the necessary toxicological experiments might be made in those laboratories without any difficulty?—Yes, without leaving it in the hands of individuals.

1249. Without leaving it to the discretion of private individuals?—Yes.

1250. (*Sir John Karslake.*) But would that apply to a case where you are obliged to try an experiment with a part of the vomit of a person who is supposed to have been poisoned?—That would be a case where I think it would be necessary to operate at once. It would be necessary, if we used it, to employ the extract at once without waiting for a laboratory for the purpose.

1251. (*Mr. Hutton.*) And without sending it up to London?—Yes.

1252. Do you not think there are very few exceptional cases where it might be necessary to break the law if the law did not permit it?—Yes.

1253. (*Chairman.*) Or would it be well to frame the law in such a manner as that provision might be made beforehand for cases of exceptional necessity?—Yes, exactly so.

1254. (*Mr. Hutton.*) You were saying that if any law were made there should be a great distinction as to the animals. Would you say that frogs, for instance, suffer less than mammals?—It is difficult to draw an inference on that point. I should rather measure the amount of sensibility and pain by the perfection of the anatomy of the nervous system; and I cannot believe that frogs suffer in the same degree as the higher class of animals.

1255. They have a vertebrate system, have they not?—They have a vertebrate system, but it is more diffused, not a system concentrated in one great organ like the encephalon, which can receive and transmit impressions. In the frog there is a distribution of nervous power over the body; a frog will jump about after his head is cut off; and frogs have a wonderful tenacity of life in their different parts; the slightest thing will excite them and set them in a state of tetanus, even sometimes merely touching them; but I do not think that this is exactly an indication of their suffering pain, but the effect of the motor nerves being more easily excited.

1256. There is an experiment without any anæsthetic given in this handbook in which the epithelium is scraped off a frog's cornea, and then nitrate of silver is brushed on to the cornea in order to inflame the cornea. Now, do you suppose that that would cause severe suffering or not?—No, I do not think it would.

1257. The frog gives all the signs of suffering—there is no question about that, I think,—in its way of using its fore legs?—The cornea itself, I may remark, is a horny substance, with not much sensation in it.

1258. There is another experiment in this handbook apparently for a demonstrative purpose. A frog is put into warm water, and the temperature is raised to about 35 or 40 degrees of centigrade; that is about 100 degrees of Fahrenheit, I suppose; and then the frog is killed; and, apparently, it is to demonstrate something on the reflex system of the frog. Is not that nearly equivalent to boiling a human being alive, having regard to the different temperature of the frog's blood and the human blood?—It is, certainly. Raising the temperature to 100 degrees in water for a cold blooded animal would be very like putting oneself into a temperature of 212 degrees.

1259. And that you would regard as a cruel experiment?—That is a cruel experiment. I cannot see what purpose it would answer.

1260. I think you said, with regard to even the very few experiments which you have ever made before a class, in the way of demonstration, that you have rather discontinued them and found them unnecessary?—Yes.

1261. So that now, even with regard to mineral acids, you do not use experiments?—No. My object there was to demonstrate to the students the destruction of parts produced by taking corrosive poisons; and that led me on a few occasions when I began lecturing to perform experiments; but I did not find that the students gained more from them than from the splendid drawings and illustrations which we have in the museum; and I have taken pains during my lectures there in every important case to have drawings and models made in order to avoid the necessity of such experiments. The models in the case of human beings are beautifully executed; and sometimes we have them in the case of animals. We have models of the stomachs of dogs, for instance, so that it is not necessary to resort to such experiments.

1262. (*Mr. Erichsen.*) The pathological appearance

A. S. Taylor, M.D., F.R.S.

14 July 1875.

as presented by the influence of the poison is shown in these models and drawings?—Yes. We have them in the horse, the dog, and a great variety of human beings, a whole portfolio of drawings; so that I have found it quite unnecessary in order to go into that point to repeat experiments.

1263. (*Mr. Hutton.*) But taking a scientific toxicologist, a man who is inquiring for the sake of science, on what scale should you imagine that he would have to experiment on animal life; how many animals would he put to death in the course of the year, pursuing his studies as a scientific investigator?—I have a great difficulty in answering that question, because it would depend upon what he was investigating. It might be the amount of poison that would destroy the life of the animal; or it might be the removal of it by absorption, and the diffusion of it through the body.

1264. But, putting aside now your experiments for the purpose of justice, on what scale would your own experiments have been performed?—Rarely more than one animal.

1265. Rarely more than one for a particular experiment, that it to say?—Yes.

1266. In the most active time of your life, what number a year would you have used for experiments?—Taking the whole 40 years I do not think I have experimented upon more than 12 or 14.

1267. So that in fact you do not think there is anything like a hecatomb of victims sacrificed for the investigation of these questions?—Certainly not in this country.

1268. Do you know anything of foreign investigations?—I have studied abroad, in Paris.

1269. Is the scale of investigation there very much larger and more reckless?—Yes. I think there the disposition is to work a great deal more by experiments on animals than in this country. I know it chiefly by repute, because my studies have been more in regard to human beings; but I have heard that at Alfort and some other places in France experiments are carried out on a very cruel scale.

1270. Are you at all well acquainted with this handbook of physiology edited by Dr. Sanderson?—I know it as a book; it is a book of very good repute.

1271. Would you mind giving me your opinion as to whether that kind of experiment is at all necessary which is mentioned at page 108, on the mesentery of a frog. Do you regard that as a very painful experiment, and as a very instructive one, and one at all desirable for the purposes of a handbook?—I think it a very painful experiment, subject to the observation that the frog does not suffer as much pain as ourselves, but still for the animal I have no doubt it is a very painful experiment, and I do not see what good purpose it would answer.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Thursday, 15th July 1875.

PRESENT:

The RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

MR. GEORGE ROLLESTON, M.D., called in and examined.

Mr. G. Rolleston, M.D.

15 July 1875.

1272. (*Chairman.*) You are the Linacre Professor of Anatomy and Physiology at Oxford?—Yes.

1273. You have taken part already, I think, sometimes in the discussion of the question which is the subject of our inquiry?—I have. In the year 1863, in an address to the Biological section of the British Association at Newcastle, I brought the subject into my address. I have here a copy of the report furnished by myself to the association's volume for that year. It runs thus, pages 109–110 of Transactions of Sections:—"Whilst upon this subject "Professor Rolleston made some remarks upon vivi- "section. A defence might be set up for it upon "the following grounds, and under the following "limitations:—Firstly, in the operations passing "under that name, the first thing done in many cases "was to extinguish life and sensibility in a manner (as "by pithing) as much more speedy than the ordinary "methods for the destruction of animals, as the scalpel "of the anatomist was a surer and speedier agent "than the clumsy tools of the slaughter-house, or "the uncertain ones of the sportsmen. In such "cases the term vivisection was a misnomer. "Secondly, chloroform was in these days almost in- "variably employable and employed; the cases in "which it could not be put into use, on account of "its introducing some chemical or other source of "fallacy, were very few. On the other hand, it was "quite open to the opponents of vivisection to say "that recognizing the susceptibility to pain which "the lower creatures had, and in addition to this, "certain rudiments in them of a moral nature as "giving them still further claims upon our con- "sideration, and feeling that we could not without "grievous injury to our own better nature make "a practice of sacrificing their lives, we were necessi- "tated to regard vivisection as something unjustifiable "and indefensible. To this it might be replied that "such a line of argument, if consistently followed "out, would lead, as indeed it had led, to vege- "tarianism, against which the instincts and even "less ambiguously the practice of the great mass of "mankind would be found to rebel, at all events at "present. And it might further be said that the "results of experiments on the lower animals had "enabled us to understand something of the nature "of, and to combat with something of success, the "attacks of two terrible human maladies, epilepsy "and diabetes. The question was a complex one, "very different considerations having to be weighed, "one against the other, one scale containing human, "the other brute suffering. Wantonness and mal- "ignity were of course excluded from our considera- "tion, whilst on the other hand the means at our "disposal for the extinction of sensibility and of life "diminished the amount of brute suffering to a "very small actual residue. Nothing, however, could "be alleged in favour of vivisection if practised "for the sake of obtaining merely greater operative "dexterity, and the whole discussion was expressly "limited to the consideration of it as practised in "England by the following words:—'In a country "'like this, where human life is highly prized, "'brute misery will never be wantonly produced.' "'The merciful man is merciful unto his beast.' It "is possible that where human life is held cheap the "man who loveth not his brother may be wanton in "his treatment of the brute. This is not the case "here; and in a British Association I need allude "no further to the matter." Also, when I presided

Mr. G. Rolleston, M.D.

15 July 1875.

over the Biological section of the British Association when it met in 1871 at Liverpool, I was entrusted with drafting a report about this subject, and those resolutions have been spoken of since as the resolutions of the Liverpool Congress. I have here an authentic copy of what was done. Those resolutions were drafted after the meeting at Liverpool, and were accepted at the meeting of the British Association at Edinburgh in the ensuing year. I understand that they are already before this Commission.

1274. You are a member of the committee for forming a conjoint scheme for medical examination?—Yes.

1275. What is that committee?—I hold their regulations in my hand, and will put them in. It having been seen to be an evil that there should be competition between examining boards for licences for practice, the Government of the day suggested that the various boards should combine, and form what is called an uniportal system for admission of candidates to the medical profession. The College of Physicians, the College of Surgeons, and the Universities, and so on, all met. We then drew up various regulations; and you know there has been a Bill before the Houses of Parliament,—the Bill under the charge of Sir John Lubbock,—which will do away with the last technical objections to the establishing of this uniportal system; and in that part which enforces the attendance upon courses of physiology we add this note, L., which stands under paragraph 12:—"By the practical course "referred to in clause 12, it is meant that the learners "themselves shall individually be engaged in the "necessary experiments, manipulations, &c.; but it "is not hereby intended that the learners shall perform vivisections."

1276. Now, were the resolutions of the Liverpool Committee in all respects satisfactory to you?—I suppose I may say, as I drafted them, that they are not; for this reason, that they have omitted any provision for the extinction of the life of an animal which has been operated on under anæsthetics, so as to prevent its wakening up into pain after the expiration of the operation of the anæsthetic. I drafted the resolutions, and I really did not know that a thing of that kind was done, otherwise I should have added it.

1277. You thought that it was sufficiently understood, but you are now of opinion that it had better be more clearly expressed?—That is just what I wish to say.

1278. What do you consider to be the object and uses of experiments upon living animals?—I should like to say before that, if you would allow me, that I think that the Liverpool meeting of the British Association did recognize very distinctly two or three very important matters, namely, that there is a great difference between the employment of vivisection for research, and the employment of it for educational purposes; and I think too, with regard to the insistance which those resolutions embody, that anæsthetics should always be employed whensoever, if ever, vivisection is employed for teaching purposes, that their insistance upon the invariable employment of anæsthetics for teaching purposes is a great step.

1279. What I understand you to say is that experiments involving pain should never be resorted to except for a necessary purpose, and if resorted to should always be performed with the greatest use of anæsthetics that the nature of the case admits of, and, speaking generally, with the greatest attention possible to humanity?—Most certainly; but I wish also to say another thing, that before more than an exceedingly limited number of individuals painful experiments should not be performed at all.

1280. What do you consider to be the necessary purposes?—I think that the necessary purposes for the employment of vivisection, not using the word etymologically, but using it in the sense in which it is employed in this Bill of Lord Henniker's, are these: Firstly, such a matter as this: if a person was found to die suddenly, or to be taken violently ill with whatever it might be, convulsions or what not, after eating say a particular pudding, it would be quite justifiable to test what the remainder of that pudding would do with a dog, or something of that kind. That is, I take it, the first necessity for it, its employment in medical jurisprudence,—the testing for poisons, which, as your Lordship will be aware, was done in Palmer's case; though there it was not a testing what was eaten, but just testing with strychnine. Secondly, I think that it may be used for testing the operation of drugs and medicines of various kinds; though I must say, speaking scientifically, that there is great difficulty about arguing from any one animal to ourselves, and also, considering what varieties of idiosyncracy there are in us, even in arguing from one man to another. No doubt you are aware, for instance, that some men are acted on by opium in one way, others are acted on by opium in another way; or, to put it still more plainly, a rabbit will eat as much belladonna as would poison a large number of men, and yet it will not act upon the rabbit in the least. Then I think the further uses of vivisection (all these being in research) are in such matters as surgical operations. Of course, such a thing as tying an artery, to show that it is possible to tie an artery, say above the knee, without starving the limb below, when it might be necessary to do such an operation for what is called aneurism, the widening out of the artery just at the back of the knee or lower down was a justifiable use of vivisection. Then certainly the functions of ourselves in health and in other kinds of disease have received considerable elucidation from vivisectional experiments. Of course, it is quite erroneous to say that all knowledge of medicine, or all knowledge of the functions, is dependent upon experiments on animals, because there is available for obtaining such knowledge the examination of dead bodies of men and of other creatures, and the comparing what is seen in the dead body with what has been observed in that body while it was yet a living machine. But it is right and fair to say, with regard to vivisection, that it has thrown light on some of the most terrible diseases of which we are the subjects,—diabetes, for example. You can produce diabetes artificially, as you can see detailed in a book which I see upon the table here, and that gives you some insight into its cause, that is to say, into the very nature of the thing. Again, epilepsy is a thing which can be produced artificially. I am speaking of vivisection as a means whereby you get all this knowledge in the way of pure research, and without any bearing upon the educational application of it you certainly have uses for it.

1281. By the word "vivisection" you throughout understand what is more accurately expressed in the terms of our Commission, "Experiments on living animals for scientific purposes?"—Yes; just what in this Bill vivisection includes, "The cutting or wound-"ing or treating with galvanism or other appliances "any living vertebrate animal for purposes of "physiological research or demonstration, also the "artificial production in any living vertebrate animal "of painful disease." It is the last sentence of Lord Henniker's Bill.

1282. But the terms of our Commission being "Experiments on living animals for scientific purposes," would include everything?—I think so.

1283. And when you use the word you do so in that wider sense?—Yes; not in its etymological sense. Then, coming next to vivisection for purposes of teaching. I cannot but think that most persons would grant that as to students of medicine, or any students, except those who intend to devote themselves to purposes of research, they should not be required to have themselves performed vivisection. In that paper, which I have handed in, you will see that the conjoint Board represents the Universities of Oxford, Cambridge, London, and Durham, the College of Physicians, and the College of Surgeons of London. Those regulations were agreed to by representatives of all those corporations; and I must say, in addition, that *à fortiori* it would be wrong to make the performance of experiments on living animals a subject in examination. They should not be required

Mr.
G. Rolleston,
M.D.

15 July 1875.

to bring certificates of having performed such experiments, and much less should they be set to do them when in an examination.

1284. In point of fact you think that students, meaning people still *in statu pupillari*, ought not to perform such experiments at all ?—I should think that with the exception of students who were going to devote themselves to physiological research as a profession, it is not a fitting educational subject for students.

1285. Would you draw the distinction that those who intended to be practical surgeons should not do it, and that those who intended to be physiological inquirers should do it ?—That they *might* do it.

1286. Do you think that this habit of making experiments upon living animals is liable to abuse ?—I certainly think it is, and from several points of view; but I should be glad first to put in a paper, which has only come into my hands within the last day or two (if your Lordship will allow me). Now, I have here a letter from Trinity College, Dublin, written to me by Professor Samuel Haughton, a man of very great scientific attainments, a Fellow of the Royal Society, and so on, in which there is a copy of a resolution carried for the School of Physic in Ireland, in which I find a note to the effect that "Vivisections are strictly prohibited" for teaching purposes. I should like to say a word on one other point. Speaking now, not as a man of science, if I may presume so to call myself, but just as a person familiar with teaching, a large part of whose life has been taken up with teaching young men, namely, on this point: To what extent is it necessary that facts should be actually reproduced before students? I think that is a point on which you would perhaps wish to hear what I have to say. There are two, or rather three, views which you may take about it. One is the view which is taken by Mr. Todhunter. He is one of the great teachers of mathematics in Cambridge. He has recently written a book called "The Conflict of Studies;" in that you will see what I think is one of the extremes, and not the right view. Mr. Todhunter says this at page 17 of that work: "It may be "said that the fact makes a stronger impression in "the boy through the medium of his sight, that he "believes it the more confidently. I say that this "ought not to be the case. If he does not believe "the statements of his tutor, probably a clergyman "of mature knowledge, recognized ability, and "blameless character, his suspicion is irrational "and manifests a want of the power of appreciating evidence, a want fatal to his success in "that branch of science which he is supposed to "be cultivating." Now, that is one view that may be taken of it. There is an entirely opposite view, and that is this: I have heard it expressed in this way, that it is actually immoral to take any statement whatever upon faith that can be verified by the eyes; which seems to me to be even further from the truth than the opposite pole which I have just put before you. That leads to profusion and extravagance in experimentation of every sort and kind, whether of a chemical or physical or biological character. I would just say this, that my own view is this, that a few cardinal experiments in any subject which is subjectable to the eyes are justifiable to enable a person, who watches them attentively, to understand the records of any similar experiments, howsoever numerous. Let me illustrate it now by this case, from a somewhat alien subject. I have been engaged myself in the study of pre-historic man, and I found it difficult to understand the description of the stratification of deposits in caves. I made it my business to go and examine one cave thoroughly, and I have now no difficulty whatever in understanding descriptions of any number. That is one way of putting it. I give that illustration just to make plain what I mean. This, I think, is a medium view, that a few cardinal experiments may be useful and legitimate for large classes, always provided that the anæsthesia is thoroughly maintained during them, and also provided that the experiment is one which cannot be sufficiently demonstrated, except upon the living subject.

1287. Is not this practice of making experiments upon living animals very liable to abuse ?—I think it is very liable to abuse. It is liable to abuse in common with many other studies, and it has also certain special liabilities which are inherent in its particular nature and essence. Firstly, it is amenable to abuse when employed for the purposes of research; and I must just say that with regard to all absorbing studies that is the besetting sin of them, and of original research, that they lift a man so entirely above the ordinary sphere of daily duty that they betray him into selfishness and unscrupulous neglect of duty. Vivisection is specially likely to tempt a man into certain carelessnesses, the passive impressions produced by the sight of suffering growing, as is the law of our nature, weaker, while the habit of and the pleasure in experimenting grows stronger by repetition. Professor Schiff says in a work of his, Leçons sur la Physiologie de la Digestion, tom. i., p. 291, 1868, that when dogs come into his laboratory, he finds it necessary to cut two of their nerves, the nerves of vocalization, the inferior recurrent laryngeal nerves, as they are called. "*Je suis obligé* "*de faire subir cette dernière opération à beaucoup* "*de nos chiens fraîchement arrivés au laboratoire,* "*pour les empêcher de se livrer à des concerts* "*nocturnes trop bruyants et de discréditer ainsi les* "*études physiologiques aupres des habitants du* "*quartier.*" It is true that it is only in young animals that this operation entails great dyspnœa and distress; still it is a grave operation in any animal, and ought not to be spoken of in terms of such levity as those quoted. Further, in a letter of Professor Schiff's in the "Times" of January 7, 1874, he distinctly says that the reason that the inhabitants of the district were not so disturbed as that French quotation says they might have been, was that there were no dogs in pain in his laboratory. Now it is perfectly clear that the statement in the book published in 1868 ought to have been shown to be reconcileable with the statement in the letter of January 1874. The matter is of sufficient importance to justify one in demanding this. I mean to say that vivisection in its application to research may be somewhat more demoralizing than other kinds of devotion to research; every kind of original research being a gratification of self, and liable to develope selfishness, which of course is the root of all unscrupulousness. Then, again, it is amenable to abuse when employed for teaching purposes. A lecturer, when lecturing, is to a considerable extent upon his trial, and he is under a temptation to set aside any considerations which may tend to impede him in just showing what he is worth. Still in teaching, a lecturer on biology is, perhaps, no more amenable to temptation than any other lecturer. I would here say that really one of the good things that lectures do in these days is, that they subject a lecturer to public opinion, and put him on his trial. I know well that into my lecture room any person may walk at any moment, and if he finds me lecturing badly, so much the worse for me. I think that in these days the lectures do more good almost to the lecturer himself than to the persons lectured to, considering the opportunities that there are nowadays of getting knowledge by books. I was saying that a biological professor is not very much more amenable to that temptation than any other person. I would just refer to Mr. Skey's work on surgery; he was a metropolitan surgeon, and has only just died; I received what little surgical education I received from him as his dresser. If you look into his work you will see this sentence: "A man "who has the reputation of a splendid operator is "ever a just object of suspicion." I have no data myself. I am happy to say that I have never seen a surgeon abuse his opportunities, or keep a patient under operation longer than needful for the sake of showing off his dexterity, or anything of that kind; but if any member of the Commission chooses to look over Mr. Skey's introduction to his book on surgery, he

Mr. G. Rolleston, M.D.

15 July 1875.

will see a good deal to this effect, which, however, is all summed up in that sentence I have quoted. Now a person who is operating upon the lower animals, who have no friends to remonstrate for them, is very much more likely to give way to such a temptation than a person operating upon human beings, who would have friends or other persons who would be made "wondrous kind" by a fellow feeling, thinking that the same thing might happen to them. But if I am to say all that I think on this matter, I do really and seriously believe that vivisection has special and distinctive liabilities and amenabilities to abuse; for it does act on our emotiono-motor nature in a particular way. Just let me illustrate this from the literary side. Canon Kingsley wrote a book called "Hypatia," in which he describes the attempt made to regalvanize into life the gladiatorial shows, and he describes the slaughter of men in the amphitheatre. When this took place under the eyes of an assembled multitude, he says, "then burst forth the sleeping devil in the hearts." You may express this by saying that this is the lower or animal nature, the unworked-out beast which exists in man. The way that Kingsley puts it is by speaking of the devil that is in the heart of every man; but, if you prefer, you may say that it is the lower nature which we possess in common with carnivora, and creatures of that sort; it is just this, that the sight of a living, bleeding, and quivering organism most undoubtedly does act in a particular way upon what Dr. Carpenter calls the emotiono-motor nature in us. Now I should wish it distinctly to be said that I know that the better class of natures are superior to this, but the very fact of their being a better class of natures means or implies that they are thus superior. A man is worse or a man is better, according as he gives way to or as he resists any particular temptation intrinsic in his own nature, or howsoever superinduced. I know that that is so, that many men are superior to it; but I beg to say that if we are talking about legislation, we are not to legislate for the good, but for the mass, who I submit are not always good. I have another point. I believe it is a fact to be accepted, that when we are massed together, we being the social and gregarious men that we are, various impulses are very much more potent upon us than when we are not so massed. It is a trite observation that people are acted upon differently by what they see in the theatre, and by the same thing as it occurs, or if it occurs, in private. When men are massed together the emotiono-motor nature is more responsive, it becomes more sensitive to impressions than it does at other times. That, of course, bears very greatly upon the question of interference with vivisections as employed before masses. I know that I am likely to be exceedingly abused for what I have just now said; but I think that nobody can demur to it who has both the knowledge and the honesty to speak of human nature as it is. Still, I should wish to fortify myself by the authority of a person who was something of a statesman as well as a scholar, a good mixture, in whatever proportions the two constituents be mixed, namely, Lipsius. Now Lipsius is referred to by Gibbon in his description, chap. xxx., of the attempt of Honorius to bring back the gladiatorial shows; it is a passage which is very well worth reading, and in fact I owe this quotation to Gibbon, and have verified it. Lipsius gave way to his antiquarian sympathies by saying something to justify the gladiatorial shows; and what he says illustrates what I now say, as he refers to our emotiono-motor nature in words which are very short and plain. This occurs in his De Saturnalibus ii., cap. xxv. Speaking of Saturnalia, at which gladiatorial shows formed part of the amusement, he says this:—"Suppose a man " is going to be executed, who does not leave his " business and run into the market place so that he " may have a look at the drawn sword of the executioner, and may look at the bleeding purple neck " of the executed wretch? *Videat et unius miseri* " *purpuream cervicem. Ita est. Queri libet de* " *perversitate naturæ*,"—These are the facts, "Blame " nature for it if you like." Without going back as far as Lipsius, one knows the trivially reported story that a butcher in France is not allowed to sit on a jury. And I may mention that soldiers will tell you that the sight of blood upon the gauntlet, that white glove which Dragoon regiments wear, to use their plain language, "wakes all the devil up in them."

1288. Then I may collect from what you have been good enough to say, that in your opinion the habit of performing experiments upon living animals is a very dangerous habit, and requires to be very specially guarded?—Quite so. I should not say that their liability to abuse should lead us to prohibit the use of alcohol or opium or chloral, or any of those things which we abuse as drugs or as food, and the cases are somewhat analogous.

1289. But that the use is one thing and the abuse is another; and there is a great tendency to abuse, and therefore the whole subject requires special vigilance?—That is quite what I think.

1290. Now do you think that there is a growth of moral sentiment in the direction of greater carefulness in the infliction of pain?—I think that is quite clear if you look at it in either of two ways. First, we may look at the history of individual minds, and I will give a concrete instance from traditions relating to the famous Haller, who did at one time practise vivisections, in his own words, *supra fidem certè numerosas*. Now, in studying Haller's Bibliotheca Anatomica, 1774–1777, for a different purpose from this, I came on a passage that struck me as extremely odd; he describes, tom. i., p. 447, a person as performing vivisectional experiments in these words:—"*Suecus* " *celebris per plurimos et vastissimos quos suscepit* " *labores, cum juvenis ex sæculi consuetudine animalia* " *viva numerosa incideret et potissime annis* 1649 *et* " 1650 *in vasis lacteis inquirendis laboraret*." "It " was the fashion in his age; he dissected a great " number of animals alive." I thought it was a curious thing for Haller to speak of its being "*ex sæculi consuetudine*;" but I had seen a statement somewhere to the effect that Haller was exceedingly careful about inflicting pain; and I interpreted the words in the sense which the much plainer utterance of Du Bois-Reymond regarding Haller's great successor, Johannes Müller, suggests: "Er allerdings nicht, wie " Einige heute thun, für das nothwendige Attribut " eines Physiologen hielt, dass seine Hände täglich " von Hundeblut rauchen."—Berlin Abhand. Akad. Wiss., 1860, p. 92. But that is not the whole story. The story is this: that as he grew older he grew more sensitive to the infliction of pain; and as is stated by Krug, (a German writer on moral philosophy, who was the author of many works, and the successor of Kant at Konigsberg,) Haller fell in his later age into a permanent anguish of conscience, which is shown in his epistles, reproaching himself most bitterly for his vivisections. These are Krug's words (Allgemeines Handwörterbuch der Philosophischen Wissenschaften, 2nd ed., 1833, vol. ii., p. 323):—"Auch der grosse " Haller hatte sich dergleichen Grausamkeiten erlaubt. " Er machte sich aber in seinen letzten Lebensjahren " der bittersten Vorwürfe darüber, und fiel in eine " Art von fortdauernder Gewissenangst, wie man aus " seinen Briefen sieht." Looking then at the date which the book I have quoted, viz., the Bibliotheca Anatomica, bears, namely, 1774, I find it was just three years before Haller's death. But I should wish to state that Haller was by no means in his dotage at that time, quite the reverse,—he was not 70 when he died,—three years later. That is the striking point; and I think I may say this (but I shall not give the name), that it is within my own personal experience, that a person who has a considerable name before the world, and has performed a large number of vivisections in his time, has expressed himself to me as exceedingly sorry that he ever did them, did them I should say to the extent which he did. The whole race has without any doubt whatever developed in sensitiveness in this direction. It is perfectly clear that there is scarcely a country in the world where such a punishment as crucifixion would be endured now; yet the Romans crucified thousands of men at once after the Servile war. And again, such a

Mr. G. Rolleston, M.D.

15 July 1875.

thing as the gladiatorial exhibitions would not be tolerated now. And this development has gone on considerably faster within the last couple of hundred years. Any person who will take the third volume of the "Philosophical Transactions," p. 522, Oct. 21, 1667, when people were repeating Harvey's experiments about the circulation of the blood, will see what was being done in France at the time. I may refer here to a number of the "Spectator" of February the 7th, 1874, in which it is said, and I believe with some truth, that human patients treated in Vienna or Paris are treated as they would not be in London or New York. Exactly the same thing is stated with regard to transfusion of blood in the "Philosophical Transactions" at the third volume, page 522, October 21st, 1667.

1291. Would you be kind enough to tell us what you think is the practical object at which we should aim?—To put it in a very general way, I should think the practical object was to put into a stable and permanent form the present wholesome condition of public opinion upon the subject. And I think the present wholesome condition of public opinion is this: that for class demonstrations, limitations undoubtedly should be imposed, and that those limitations should firstly render painful experimentations illegal before classes. I am loth to say anything about interference with original research; firstly (perhaps this might also be lastly), because I think it is impossible to so interfere with it. I am not entirely clear as to whether knowledge can or cannot be bought too dear; I will not pronounce myself upon that; but this I am quite certain that *de minimis non curat lex*, that what individuals do is not necessarily a thing upon which legislation should determine itself. But legislation is called for when numbers are concerned.

1292. But supposing that anything which can fairly be called atrocious is practised by an individual, do not you think that society would have both a right and a duty to restrain it?—Most undoubtedly. But are there not some acts which would just bring a person under the law for atrocious cruelty? I have not the knowledge of the law about that. What I am clear about is the positive side, that legislation is expedient and advisable, and called for with reference to class demonstrations. With reference to the other point, that is really a matter not so much for me as for people who can judge of what is possible and practicable; for instance, a wise governor of police who knows to what extent you can go into private houses, and what not.

1293. I think, if you will allow me, we will endeavour to obtain from you (and I think we are arriving at a just appreciation of your sentiments, what are the objects that society should aim at in the first instance; then afterwards we should be glad of any suggestions which may occur to you as to the mode in which we should recommend society to endeavour to arrive at them. Now what I understand you to say is that you think that experiments may be very much diminished in number without any injury at all to science?—Certainly.

1294. That if performed upon living animals they ought to be performed with anæsthetics in almost every case?—Certainly.

1295. That whatever is the most humane thing that can be done ought to be done?—Yes.

1296. That many persons, like, for instance, Haller, as they get more experienced become more sensitive to the mischiefs which in their earlier years they did not so clearly perceive?—I do not quite think it depends on experience in the particular person so much as on that development of the moral sense which one sees in individuals. A child will pull off a fly's wing and we think little of it; but if any one of us was to do it we should consider it very strange. It is not experience of a scientific kind but the evolution of the moral sense as a man gets more knowledge of the world at large, and so on.

1297. I may put it in this way—a man in his wiser times will condemn, as Haller did, that which in his younger times he practised?—Yes, I should be glad to say that.

1298. If, therefore, society is wiser than the individuals, we may be encouraged, by such examples as Haller's, in bringing the forces of society to bear upon the individuals?—If you can get them to bear on the individuals, certainly.

1299. Therefore, the object in view I think we have arrived at; and now the most important question for us is whether you can make any practical suggestion to us as to any particular mode of proceeding, or any limitations upon any mode that we might otherwise be inclined to pursue. Now, you would not allow in a lecture room the exhibition of pain before the pupils?—No.

1300. You would consider that demoralising to the pupils?—Certainly.

1301. In regard to individual research you are afraid that it may not be easy by any legislation to coerce an individual?—Of course it is very much more difficult to deal with a man within four walls and by himself than it is in a public place; that is all I mean.

1302. (*Mr. Forster.*) You mentioned two diseases in which advantage has been gained by experiments, diabetes and epilepsy. In what way has that advantage been shown in epilepsy?—Well, it is not so much in the ponderable advantage of therapeutical dealing with it as in that insight into its essence which may one day or another, we may hope, lead to some therapeutical improvements. As far as I know, that is the condition it was in when I left off practice; that is now some ten years ago. Ætiology had gained rather than therapeutics.

1303. Coming to practical suggestions, we have had before us the suggestions of making experiments on living animals illegal, even for the purposes of research, unless in licensed places and by licensed persons. What do you think of that suggestion?—As I said in answer to Lord Cardwell, that is rather a question for a person who understands interference of a domiciliary kind than for me. To what extent would you find it practicable to supervise a man in a study with doors and what not between him and the outside? What I do think is that a law should aim at what is practicable and verifiable in its results; but really I am speaking now on a subject which is not quite my own. I am quite clear of this, that any legislation in favour of restriction of the practice in one application would assuredly bear fruit in another; and if it was made illegal to abuse it in public, and before pupils, that would be a fixed point gained in the gradual evolution of moral tone upwards: that is my feeling.

1303*a*. But I rather gather that you think it would be very difficult to get a law that would be effectual, which would interfere with the research of a scientific inquirer in his own study?—I must say that my own impression of the English nature is that it is a law-abiding nature, and that a pronunciamento on the side of carefulness, even as regarded private practice of vivisection, would have its effect.

1304. (*Sir John Karslake.*) I gather from you that in your opinion some restriction put upon the practice of vivisection in schools would have its effect upon the practice of vivisection in private houses and for private research?—I think so; on the principle that Mr. Froude, I believe, lays so much weight upon, about embodying the public opinion in the permanent form of legislation. That is a great matter. It, so to say, crystalises it into a solid basis which serves as a stepping stone in the evolution of moral sensibility upwards.

1305. May I take it that you would not recommend that all private research for *bonâ fide* scientific purposes should be prevented?—I should not wish that it should be prevented; but I will not say that I think it would be inexpedient to legislate for it as well as for the other. I do not feel so confident as to the good that would be done by legislating for it in private, Mr. G. Rolleston, M.D.

5 July 1875.

as I do about the legislating for it as regards public classes.

1306. Now may I ask you this: in your opinion is there no case in which experiments of this sort should be tried before classes?—Painful experiment should not be tried before classes.

1307. None whatever?—None whatever of the painful ones. I would just say that there is a great difference I am sure between an experiment shown to three or four people and one shown to thirty. It may seem absurd to say so, but I am confident that it is so; and I would repeat with Lipsius—"*Ita est.* "*Queri libet de perversitate naturæ,*"—"You may "complain of the perversity of nature, but that is what "nature is."

1308. Then as I understand it, in addition to allowing experiments of this sort for the purpose of private research with a view to scientific conclusions, you would not object to them where the exhibition of the experiment was made between three or four persons who desired to see the experiment made, and had a real object in wishing to see it made?—Yes, that is, I think, the position I should take.

1309. But the objection you would have would be to allowing a large number of students *in statu pupillari* to see the experiments made?—If it was a painful one.

1310. (*Mr. Forster.*) Does that mean that although you would think it unadvisable to allow, or rather that you would prevent experiments before a class of the size of which classes generally are, you would not object to the teacher doing them before his pupils in smaller groups?—Yes, I should certainly; because the addition of three, four, five, six, or seven classes in that way would of course be equivalent to the whole thing, and that would simply be an evasion of the rule. What I mean is just this: that it is possible that under certain circumstances it may be for the public good, and may be legitimate that two or three advanced students, not students working for an examination, but students of the other kind, the men indicated by the word "students," should assist the professor in original research; and now I would say that it might be advisable that legislation should be employed for such exhibitions as those, but that in their case the legislation should be less stringent. It is clear that it is an impossibility and a contradiction in terms to think that you can have a lecture room full of students who are going into original research; out of 100 men or even 100 men who are students it is a question whether you will find one who has a gift for original research.

1311. (*Sir John Karslake.*) You would not object to persons either alone, or with the assistance of one or two others, practising these experiments with a *bonâ fide* view to scientific research?—I would not.

1312. Then you would object to legislation directed against that state of things?—I am not clear that I should object to it; I do not feel myself prepared to object to legislation for that. What I have made my mind up about is the positive thing that it is right that legislation should affect classes. And now that you bring me to face this question (not more directly than I have faced it before, but by going over the ground again and again, one gets precision in one's views). I think that legislation might be brought to bear even upon that other application of vivisection.

1313. (*Mr. Forster.*) Should I be right in gathering from what you have stated that while you would by legislation prevent painful experiments on living animals in the presence of classes as usually constituted, you would also advise legislation with regard to experiments for research, either by one man or by a man assisted by advanced students, but that in that case you would not advise absolute prohibition, but only some regulation?—Quite so; that is the view of it that I have come to and tried to express.

1314. (*Sir John Karslake.*) Going back for a moment to the exhibition of these experiments in schools, you say that you would not allow painful experiments there?—No.

1315. Would you allow experiments which might be considered necessary, and which could be performed when the animal was under anæsthetics?—If it is certain that the animal is under an anæsthetic, and if it is also understood, as I have said at the commencement of my giving evidence, that the animal is put out of life before it returns to sensibility, the animal may then practically be considered as dead, albeit for physiological purposes it is a living machine.

1316. In order to see what would be done by way of legislation, you have to define in what cases these experiments might be made before a class?—I should doubt whether legislation should do that. I think that profusion and extravagance should be guarded against by legislation even as regards experiments performed with the precautions specified.

1317. But could you give us any form of words which would meet your view with regard to that, so as practically to have the effect of preventing excess while permitting experiments up to a certain point and under certain conditions?—I have not considered the subject quite practically. Perhaps it would be necessary to have something like a standing provision, that there should be returns as regards experiments performed in any particular laboratory before students.

1318. Do you think the case would be met by providing that in every school of this description there should be a register made of the experiments which are from time to time made in the school, and the reasons for which those experiments are performed, or the objects for which those experiments are performed?—Yes, that is what I meant.

1319. Would that in your judgment be sufficient with the aid of public opinion to prevent abuse?—Let me say that I have a school of human anatomy in my hands. If I go down as I intend to do to Oxford tomorrow I may meet one of my servants when I go into the museum who will say to me "the inspector of anatomy is here." If so he has come without any consultation with me at all, and has just come to see whether any abuse has been perpetrated. I am entirely amenable to inspection, and have no right to feel in the least annoyed by it. I think that in addition to a register, inspection of some kind is a thing which is desirable.

1320. That there might be the power to allow an inspector at any time he thought right to enter these schools to see what was going on?—Yes, and that in addition to that a register should be kept. I send a register of all bodies dissected, though they are dead ones; and in addition I am amenable to the visit of an inspector.

1321. That gives us a definite notion of what you would propose with regard to these schools?—I have not considered that point as fully as I ought to have considered it, and consequently I am not prepared to say in a matter of detail of this kind that that is the wisest plan for securing it. It is a plan which I have heard of before, and I do not see any objection to it at the moment; but, of course, if I had more time to think over it I might or I might add to or alter it.

1322. I do not ask you to pledge yourself to that being the best plan; but it would be a plan which would go in the direction which you would wish?—Yes.

1323. That plan would not apply in any way, as far as I can judge, to the case of those who in their own houses make experiments with a view to scientific information, private research as you have called it?—No.

1324. Does it suggest itself to you that there could be any legislative control in those cases?—I really am of opinion that most experiments worth doing would be done in a public laboratory, and that very few cases of experimentation in private houses would take place at all; and consequently I think that no great inconvenience would arise from compelling all experiments to take place in a respectable laboratory, a laboratory amenable to the visits of an inspector.

1325. No inconvenience would arise from that you think?—Very little. Of course it is possible that

Mr. G. Rolleston, M.D.

15 July 1875.

you might have people, such as Mr. Boyle was 200 years ago, who might wish to start a private laboratory, and so on; but then *de minimis non curat lex.*

1326. Then it may be that legislation would not be expedient in those cases, because they are among the class which you describe by the term "*de minimis?*"—Still the inconvenience that persons would experience, who would start laboratories if there was no provision of the kind supposed, would be so small that it would not be a thing which should weigh in legislating as to having experiments performed in places amenable to inspection.

1327. Let me put a case to you which has been put before this Commission. A person living in a remote part of the country suddenly dies with symptom of poison, after having partaken of some particular food. A medical man, living at a distance from any laboratory, such as you suppose might exist in the country, tries the effect of that food, which was supposed to have caused the death of the human being, upon an animal, in order to ascertain whether it would cause death by poisoning in that animal. Would you say that legislation should interfere with that experiment?—I should certainly have thought that as men run to and fro by steam, and knowledge is increased by the electric telegraph, the suspected thing might be sent up instantly to a laboratory. Certainly in these cases we have had abundant evidence that things can be sent up to experts in medical jurisprudence; and *ipso facto*, if it is in a lone and desolate country, is a person there likely to have the means and appliances for testing a poison available except such as giving it to a dog?

1328. That is the very thing I am suggesting, that you would give it to a dog or a rabbit for the purpose of ascertaining whether it causes that animal to die, apparently with symptoms of poisoning?—Very few poisons, except such as prussic acid, are volatile or decomposable in such a way as not to be testable afterwards; and even that is preservable for testing purposes. But I should have thought that a case of that kind is not one that should guide legislation, for it can but happen in the very nature of the case very rarely.

1329. But supposing you lay down some rule, such as I understand you to suggest, that no person shall, even for the purposes of private research or experiment, perform an experiment on a lower animal, except in a public laboratory, or an authorised laboratory, then you know the person who performed the experiment, which I am suggesting for a *bonâ fide* object, would come within the law, and be liable to the penalties of the law?—I quite see that; but then I must say that that which is the third recommendation of the Liverpool Congress is one which I never felt very strongly about. I do not feel it to be of the same cardinal consequence as the other thing. I see that there are difficulties that beset that. Then in these questions you must weigh one set of disadvantages against another, I apprehend.

1330. I only wanted to know what was the balance in your mind; would you still say that there should be no private research at all, except in authorised or registered laboratories?—I should be sorry to say that, I think.

1331. (*Mr. Forster.*) Do you not think that it would be possible by law to say that there was to be no such research, except in authorised laboratories, and to make a proviso that the penalty should not apply in the case of an experiment made with regard to any person who had been poisoned?—Quite so. You are good enough to supply me at once with the answer; but I again say, in justice to myself, that it is not my business to give advice about police regulations, and what you have suggested seems to me to cover the case.

1332. (*Mr. Erichsen.*) Have you been able to form any opinion as to the extent to which experiments on animals are carried on in private?—No; but I do know that experimentation on animals is carried on in private by scientific men.

1333. Could you give us any information as to the physiological laboratory at Oxford? Are you connected with it?—Yes; I am the professor of anatomy and physiology, both.

1334. In that laboratory are students,—I mean students *in statu pupillari*,—allowed to make experiments, either independently or under the supervision of the teacher?—No, no student *in statu pupillari* has anything to do with experimentation on living animals in the University Museum in Oxford.

1335. And it would be erroneous, I suppose, to say that there was anything like a reckless system of experimentation carried on at Oxford?—Most assuredly; I should be responsible for whatever of the kind was done in the university department of physiology.

1336. Perhaps you would kindly explain to us the way in which the experiments are conducted in that laboratory?—I do not show students who are going to be examined, who have that sword of Damocles hanging over their heads, experiments upon living animals at all. As a matter of fact, I might refer to evidence of mine in reference to the necessity for increasing the professoriate at Oxford, and that there should be not only, as there is at present, one professor to deal with two subjects, but two professors to deal with the two subjects of anatomy and physiology. Some few experiments on living animals have been carried on in my laboratory, but they have not been for students *in statu pupillari;* and then one and all were for research, or every now and then there may have been one for showing some cardinal point of physiology. They have been carried on under anæsthetics.

1337. The "students" in point of fact, then, are medical men who are studying the higher branches of the profession?—Not quite medical men. At Oxford a large number of my students are not going to be doctors at all. Sometimes half may have been persons who were going to take, say science masterships in schools, or something of that sort, or persons who simply saw their way to their B.A. degree through a science curriculum. We have that anomaly, and a very useful one it is, that persons can get a degree in arts by a training in science; and those come to me, a number of them, and others go to chemistry and physics.

1338. What you stated with regard to the emotional tone of mind induced by large assemblages of pupils witnessing experiments would go further, I take it, than experiments on living animals; it would apply also very much to the witnessing of operations in operating theatres?—Yes, I think it does.

1339. (*Mr. Hutton.*) You were saying that you thought there was a distinct growth of moral feeling in favour of greater care to avoid the infliction of pain. Now you apply that remark rather, I suppose, to the growth of centuries than to the last few years?—It is rather the reverse, I should think, within perhaps the last few years. There are eddies in a river which is flowing from east to west, but it is flowing from east to west all the same.

1340. But do you not think that the introduction of so many physiological lecturers who have studied on the Continent has produced a school of quite a different character in the physiology of the present day in England?—I should like just to say this upon that point: Dr. Child, who has been a practising doctor, and is now an exceedingly useful inspector of health (he has one of the large divisions, viz., Oxfordshire), wrote a book about some 10 years ago, in which he dealt with this subject of physiological experimentation. I had some talk with him about it, and he said to me distinctly that if he had now to write that essay over again, he should recommend legislative interference, which he then thought was not necessary. He has written a book of physiological essays and so on, and is a person of an active mind, and also he has a quantity of business to transact which brings him

Mr. Rolleston, M.D.

July 1875.

into relation with other men on questions of this kind. I presume that answers your question.

1341. (*Mr. Forster.*) And did he come to that opinion because he thought there was so much greater inclination to try experiments that the necessity for legal regulation was greater ?—That is just the case. I may add that I asked him whether I might quote him, and I asked him whether he would be prepared to give evidence before the Commission to that effect, and he said he should be very glad to do so.

1342. (*Mr. Hutton.*) You gave us the idea that your own experiments have been on a very moderate scale indeed ?—Very.

1343. Can you give us any idea of the actual number of your experiments on living animals in a year ?—Some years there are scarcely any at all. I do not profess to be an experimental physiologist, and I do not think that the educational value of it would be great for my purposes, for I am not more a teacher of young doctors of the future than of ordinary English gentlemen. I have an human anatomy class; but certainly I do not profess to teach experimental physiology, that is to say, if "Physiology" is to mean what it is made by some professors of it on the Continent, namely, nothing but vivisection. If you take that book of Schiff's up, you will find that almost every lecture has some animal sacrificed for it; there are 700, that is more than two a day experimented on, according to report, every year there.

1344. I am going to ask you a question on a rather delicate matter, but do you not consider that this handbook before us introduces quite a new enlargement of the practice of vivisection into the teaching of physiology ?—No doubt; but I should say about that, that I am very well acquainted with one of the authors of it, namely, Dr. Michael Foster; he is a person of, it seems to me, an exceptionally refined mind, and what is safe for a man of an exceptionally refined mind is not safe for the ordinary mass of mankind, and it is with the ordinary mass of mankind that legislation deals.

1345. I have often heard that about Dr. Foster, and I believe it to be perfectly true; but amongst his experiments there seem to be some of the most questionable, and, as far as I can see, some of the most needless that are found in that book. Now take the experiment on the reflex action of a frog at page 409 :—"As an instance tending directly to the contrary supposition, the following experiment may be performed :—In a shallow glass or porcelain dish, place enough water to reach up to the head of a frog. Line the sides and bottom of the vessel inside with felt or blotting paper. Place an unmutilated frog in the water, and then gradually raise the temperature. Cover the top of the vessel with a piece of guage or netting, to prevent the escape of the frog. As the temperature rises the frog becomes uneasy, and after 20° C. or 30° C. is reached, makes violent attempts to escape," and so on. I suppose that that frog is practically boiled alive, is not he ? 35° centigrade is, I suppose, practically much the same as about 95° or 100° Fahrenheit, is it not ?—Yes.

1346. Having regard to the low temperature of the frog's blood, that is very much the same as if we were put into boiling water, is it not ?—Well, I am not quite clear about that. Albumen is albumen and coagulates at 140° of Fahrenheit you know, which is considerably above it, and the boiling point 212° F. is necessary for producing a blister in us. A frog would be killed, as cold-blooded animals usually are, by continuance in a medium such as water at 100° F., but it would not be boiled or blistered. I am not quite clear that that is an experiment, such as you would call "most questionable," but I should say it was needless to repeat it. While you are on this point, I do not know whether I ought to say it, or not, but I spoke to Dr. Foster about one experiment which is frequently referred to, one mentioned at page 403, of testing recurrent sensibility. Now Dr. Foster himself told me that not only had he never shown it to any of his pupils, but that he had never seen it himself; and I must say that I should be sorry to see that experiment myself.

1347. But surely it is put here in a handbook in a mode which would encourage the trying of that experiment ?—Obviously. I am speaking in vindication of the character of a friend of mine, but not at all in vindication of the book.

1348. (*Mr. Forster.*) You have read that handbook ?—Yes.

1349. It would give me the impression, and I should like to know whether you think it would be a correct one, that experiments on living animals are suggested there in just the same way as any other experiments might be suggested ?—Yes. I should like to say with reference to the amount of anæsthetics employed, that I have tried myself a number of experiments upon the action of anæsthetics, and I must say that it is not so easy a thing to know when you have an animal thoroughly anæsthetised; and what is more, some animals recover with much greater rapidity than others of the same species from the same doses of anæsthetics.

1350. Many of the experiments there are suggested to be performed under curare; would you consider that an anæsthetic ?—The very Handbook itself shows it is not if you look at the experiments about it, p. 395–396; but I would say this, that I am informed that there quantity comes in. I have done experiments myself with a small quantity of curare, enough to make the animal quite quiet; and then it would recover from it, and there was nothing painful done after it. I beg to say this, that I am strongly inclined to think that a very large dose of curare would be probably an anæsthetic. But I must say that the whole question of anæsthetising animals has an element of uncertainty about it. Some animals are, some are not, within the limits of the same species, amenable to anæsthetics just as we are ourselves.

1351. (*Mr. Hutton.*) Then I understand that your opinion about the handbook is that it is a dangerous book to society, and that it has warranted to some extent the feeling of anxiety in the public which its publication has created ?—I am sorry to have to say that I do think that is so. I do happen to know not only Dr. Michael Foster but I know also Dr. Sanderson, though I do not know him as well; but I think that their book represents them as being something other than I happen to know one of them at all events, Dr. Michael Foster, is.

1352. But now, in that book the experiments on frogs are very frequent, and very many of them I find are performed under curare only ?—I daresay that may be so; but I think if you look at the beginning of Dr. Foster's part of the book you will find that he does pith frogs.

1353. He does in some cases, but not in all ?—The particular department he has dealt with, the electro motor department of physiology, is not one that I am an adept in. I have read what he says, but it is not one of my subjects. It ought to be, perhaps, but it is not.

The witness withdrew.

Mr. J. Simon, F.R.S.

MR. JOHN SIMON, F.R.S., called in and examined.

1354. (*Chairman.*) You are the medical officer of the Privy Council and the Local Government Board ?—I am.

1355. You are a surgeon, and a Fellow of the Royal Society ?—Yes.

1356. Has your attention been particularly called to the subject into which we are appointed to inquire ?—It has.

1357. Chiefly, I think, pathologically ?—Chiefly so, of late years.

Mr. J. Simon, F.R.S.

15 July 1875.

1358. Perhaps you can give us a few illustrations of the subjects which in your official capacity your inquiries have been particularly directed ?—In my official capacity I have to think chiefly of the prevention of disease. For the prevention of disease the first necessity is to have knowledge of causes, the more exact the better; and in working out exact knowledge of causes of disease it is occasionally requisite, in parts of the subject, to administer experimentally to animals the influences which we are studying in that relation.

1359. I believe the particular subjects which have occupied you are cholera, tubercle, pyæmia, sheep-pox, and disinfectants ?—They have been among our chief subjects.

1360. I think there is an annual grant made, of which the distribution falls under your charge ?—There is an annual grant of 2,000*l.* to the Privy Council Office for scientific investigations in aid of medicine.

1361. Speaking broadly, how is that divided ?—At present the 2,000*l.* is first of all divided into two halves. The one half would have nothing whatever to do with the present question; it is spent entirely on work of the chemical laboratory. Only the other half is in that class of studies where sometimes experiments on animals would come in.

1362. Namely, anatomical ?—Rather, pathological.

1363. Is a great part of that done with the dead subject ?—A great part is on the dead subject.

1364. What sort of proportion do you think is on the living subject ?—I have no way of stating proportions exactly, but I would give you some illustrations of experiments which have been performed on living animals. A few years ago it was necessary for us to follow, as far as we could at that time, the subject of the infectability of animals by choleraic discharges; and a considerable number of experiments were then performed by the administration of extremely minute doses of cholera-discharge to the subjects of experiment. The subjects of experiment were mostly mice.

1365. Then there was no pain of the knife in cases of that kind, I suppose ?—No pain of the knife.

1366. Any distress that was caused there was distress from other causes ?—Bowel complaint.

1367. Are there any rules or minutes of the Privy Council which govern the application of this money ?—At the end of 1873, when I was making a provisional report of some of our work, forestalling that which was last year laid before Parliament as No. 3 of the new series of my Reports, Mr. Forster made a special note on the use of animals in some of the investigations. His observations were the following:—“Upon being informed that there were experiments on living animals connected with the Auxiliary Scientific Investigations, I had to consider how far I could make myself in any way responsible for these experiments. After careful consideration, I came to the conclusion that however much I might dislike vivisection I should not be justified in preventing it if practised, not only for the purpose, but with the reasonable ground for expectation that it may result in discoveries which will diminish disease in men or other animals, provided that every precaution against pain be taken of which the experiment admits. As such discoveries are the object of these investigations, and, indeed, of the vote, I felt I could not require these experiments, when really necessary, to be discontinued; but I thought it right to require that they should be conducted with every endeavour to avoid pain, and especially with the use of chloroform or other anæsthetic. I found that these experiments were thus conducted, as indeed I expected would be the case, knowing as I do the desire of Mr. Simon to avoid giving pain to any animal; and it is therefore merely as a justification for myself that I desire to have on record the opinion upon which, had I remained in office, I should myself have acted, viz., that no experiments on living animals should be conducted at the cost of the State without the employment of some anæsthetic in case of painful operation, and without a report from time to time by the gentlemen conducting the experiments, explaining their object, and showing their necessity for the purpose of discovery.” That is dated the 17th of February 1874, and signed “W. E. F.” It, of course, subsequently came under the notice of Mr. Forster’s successor in office, Lord Sandon; and for his and the Duke of Richmond’s information I afterwards submitted an explanatory minute which I am now authorised to lay before the Commisson. It is dated February 26th of this year, and is as follows:—“In modern endeavours to increase the power of preventing different diseases of man and domestic animals, usually a first aim is to obtain exact scientific knowledge of the causes and the mode of attack of any disease which is in question; and in this sort of study it frequently happens that more or less experiment has to be made as to the results which the administration of a particular influence will produce on an animal. In further aid of preventive medicine, and often in aid of therapeutics, experiments on animals are also from time to time wanted, to test, as against known causes or processes of disease, the value of alleged prophylactics, antidotes, and remedies.—Studies of this experimental test are made sometimes more immediately in the interests of man, as, for instance in the case of Asiatic cholera, and sometimes more immediately in that of the domestic animals, as in the cases of sheep-pox and cattle-plague, but perhaps oftenest in the common interest of both; for, in regard of certain large quantities of disease, it may be assumed that any better knowledge which is got will probably sooner or later yield equal advantage to human and to veterinary medicine. If in such experiments it were ever necessary to perform on any animal any severely painful operation, chloroform or other anæsthetic ought of course to be used; but, in fact, experiments of the class referred to have generally consisted only in inoculating animals (by mere puncture) with some specific material, or in giving to them in their food the material of which the effect has had to be watched, and perhaps afterwards taking from them blood for examination, operations which in themselves are little or nothing more than the vaccination or bleeding of the human subject. No doubt, however, but that pain or uneasiness will afterwards arise in cases where disease is the result of the experiment; but in experiments which are not of curative intention, the experiment would often require that the animal should be killed for examination as soon as disease had become manifest, and of course no animal would needlessly be let live in a state of suffering.—That experimental studies of disease are of the utmost importance to the progress of medicine, that indeed such progress must at present in large proportion depend on them, is, in my opinion, quite certain. For myself I may say, that, obliged as medical adviser of the Government to make myself as proficient as I can in all that relates to the preventing and resisting of disease, I have felt it indispensable that I should have recourse *inter alia* to such studies; and in some of the Scientific Investigations which are made under authority of the Privy Council in aid of pathology and medicine, and which I have the honour of superintending for their Lordships, such studies have necessarily formed a part.—I can confidently say that in any experimental use which has thus been made of animal life in the medical interests of mankind, conscientious regard has always been had to the limit within which such use can alone, in my opinion, be justified. In view of the universal practice of mankind in other relations to the lower animals, and under sanction as I believe of sound reason, it has been assumed that, for the sufficient advantage of man, suffering may be inflicted on brute animals; but the limitations have been well remembered, that no such suffering should be inflicted except in endeavours for considerable human advantage, nor except with all proper care to make the suffering

Mr. J. Simon, F.R.S.

5 July 1875.

" as little as can be.—At the end of 1873, on occasion " of a provisional statement which I then made (and " which has since been embodied in a report laid " before Parliament) on the scientific investigations " which were in progress under the Privy Council, " Mr. Forster asked me to explain to him how I " stood in regard of the performance of painful " operations on animals; and on the explanation which " I then gave to him in accordance with that which " I have here written, he wrote remarks of which copy " is above. I communicated Mr. Forster's minute as " an instruction to the gentlemen who act with me " in pathological investigations." Adverting to the change of ministers which has taken place, I may mention that of course Mr. Forster's minute is still understood to be in force. In the present connexion it may be convenient that I should now put in a return recently moved for by Mr. Dillwyn showing our last four years investigations. It is No. 223 of the present session, and is dated 27th of May 1875. [*Paper handed in.*]

1368. That opinion which you have expressed, and which I may divide into two parts, namely, first that such experiments are necessary, and secondly that they ought to be conducted with all possible regard to humanity, I understood you to say that the general opinion of the eminent medical men of this country would concur in ?—Certainly I believe so, but I say this with special reference to such of them as have thoroughly considered the subject. Some eminent men may have never considered parts of it.

1369. Do you consider that the practice in this country is extensive ?—It must be confined, I should suppose, to very few persons.

1370. And those the most competent ?—Yes.

1371. And ought to be so confined ?—Yes.

1372. Do you think it is increasing ?—Parts of it are probably increasing, other parts probably diminishing. I should think that probably the more painful sort of experiments which I dare say the Commission has had particularly in view, and which may be described as severe surgical operations on the animals, are both greatly fewer in proportion to the number of physiologists, and greatly fewer in proportion to the range of physiological research, than they were in the times of Magendie.

1373. Then upon the whole, of operations which are in themselves calculated to produce severe pain, you do not think the number is materially increasing? —I should think not. It is very difficult to judge that, and I cannot profess to speak with certainty.

1374. And then the introduction of anæsthetics must have materially affected the question which we are considering ?—Very materially.

1375. May almost all severe surgical operations of this character be performed when the animal is entirely unconscious ?—I should think nearly all, certainly a very large majority.

1376. And as to the rest, is it possible to perform the severe parts under anæsthesia, although the result afterwards may not admit of the continuation of the anæsthesia ?—Yes; local anæsthesia can also, in some cases, be produced where general anæsthesia could not be.

1377. Is it your opinion then that very few operations could now be justified on the ground that the infliction of severe pain was a necessary element of the experiment ?—The Commission would have better evidence on that point from the actual prosecutors of such experiments, or from some chief modern physiologist, such as Dr. Sanderson, than it would have from me. My impression is, that it would rarely be necessary for a physiological purpose that the animal should continue sensible to pain during a severely painful operation.

1378. Now such being the state of the case, and such the general sentiment of the eminent and competent men of the medical profession, do you think that there are any other persons who are neither eminent nor competent, and who may nevertheless be disposed to resort to these practices ?—I cannot say that I have any experience of such. There may perhaps be imagined an occasional boy or girl who tortures a dog or cat under the notion of doing physiology; but I can hardly conceive anything of the kind. I have no reason to believe that it exists to any appreciable extent.

1379. Then your belief would rather be that, if it were represented to us that experiments of a severe character were repeated, when there was no real necessity for the repetition, that is a mistake ?—I should think so.

1380. And if it is said that experiments, which might be performed under anæsthetics, are performed without care being taken to render the animal unconscious, you would imagine that that is a mistake too ?—Generally speaking, yes. There may be individual acts of carelessness: extremely few, I should suppose, in regard of any domestic animal; but more likely to occur in regard of frogs, as they are of far larger use for physiological purposes, and perhaps are also often ranked as less sensitive. I think one advantage of the sitting of this Commission may be that those of us who have in any way to use animals for purposes of experiment will ask ourselves even more strictly, whether we are doing all that we ought to do, all that we can do, whether we could possibly go further than we go, in preventing pain where we perform experiments. But I believe that as a rule much care is already taken to prevent pain to animals in severely painful procedures, and that at least in regard of domestic animals any such procedure would hardly ever, if ever, be undertaken except with use of anæsthetics.

1381. Naturally, as far as you are yourself personally acquainted with them, the experiments are in the hands of those who act in the spirit of the memorandum that you have been so good as to read to us, and you think that the most eminent and the most competent people in the country all act in the same spirit; but, of course, it is possible that there may be persons who think they are doing some good in practising these sorts of experiments, and who are not of the same either competent instruction and right minded sentiment as the eminent persons of whom you have spoken; but you are not aware of such; you do not think that there are any ?—Not as an appreciable class.

1382. Therefore your opinion is that the necessity for measures being taken by the Crown or by Parliament is not nearly so great as has been held out to the public of late ?—I think certainly not. It has seemed to me that the public has been led to form extremely exaggerated views of the extent to which the sort of thing is done in this country, and has not been made aware that, where it is done, it is done under reasonable precautions.

1383. If there were to arise sufficient evidence of such abuse, do you think that the competent persons, of whom we have been speaking, would be as ready, as any other eminent persons in the country, to support the Crown and Parliament in reasonable measures for the repression of those abuses ?—Certainly.

1384. But you have not yourself any belief that the necessity has arisen ?—No.

1385. Then I suppose you have not provided yourself with any proposals for remedies, as you do not imagine the necessity to exist ?—I have not. I have looked at the Act of 1849 for preventing cruelty to domestic animals, and at the two Bills which have recently been before Parliament. The Act for the prevention of cruelty to domestic animals was founded on a previous statute of, I think, 1836, and the preamble of that Act takes as its basis, that "many and great cruelties" are practised in driving and conveying cattle, and in slaughtering them, and keeping them without food and nourishment, "to the great and needless increase " of the suffering of dumb animals, and to the de- " moralization of the people." I have not a conception that there is anything answering to those terms which purports to be for the sake of physiology; but were it so, I would observe that under the Act it

Mr. J. Simon, F.R.S.

15 July 1875.

is made punishable to "torture" any domestic animal, and that if a physiologist should do an act which could properly be described as "torture" of a domestic animal he would apparently be within that provision of the law.

1386. (*Sir John Karslake.*) To cruelly torture any domestic animal, if you look at the whole sentence?—And the "*cruelly*" enables me even better to explain my meaning. I presume that it is open to any one to take proceedings under that Act of 1849 against any one found causing pain to any domestic animal for purposes declaredly physiological; and it would then be a question whether the causation of pain could be defended. It would not, I apprehend, be enough to declare that the intention of the procedure had been physiological. I presume that before the magistrate the person charged might fairly be called upon to show, (1) that he had a reasonable prospect of scientific use to mankind from the study in which he was engaged, and (2) that he was personally of competent skill and judgment in the study, and (3) that he had not wilfully or negligently omitted to use proper care for the prevention of the suffering to which his operation or experiment tended. I presume that such showing as this would exonerate him from any charge of having "*cruelly* tortured" under the Act; but that with failure to show to some such effect, the physiologist, like other men, would be punishable. Supposing that to be a right construction of the Act, I do not see what more should be wanted; but if that is not a right construction of the Act, I should not myself see the least objection to a statutory declaration in some such sense.

1387. (*Mr. Forster.*) Would the Act apply to many of the animals upon which experiments are performed, such animals not being domestic animals?—It would not apply to frogs.

1388. (*Sir John Karslake.*) Nor to white mice?—Nor to white mice. I do not doubt but that, as regards the question of moral obligation, frogs and mice ought to be safe against cruelty; but law does not pretend to be co-extensive with morals; and as regards the question of law, I do not see how the Legislature can intend to take care of other than domestic animals. Probably it will find even that a larger task than it can successfully manage; but, since the Act of 1849 affirms that as its principle, there could not I apprehend be any objection if it were thought necessary to explain the Act in relation to physiology in some such sense as I have suggested. Further than that I do not see how the law could go without going into unpractical refinements on the subject, and having sooner or later to draw a new arbitrary line where the grounds of distinction might be far less definite. Without referring to the fact that the limits of the animal kingdom downwards are somewhat uncertain, I may point out that there is no reason in the nature of things why a man should be allowed to torture, say, a slug or a snail rather than a rabbit. Lord Henniker, I think, draws his line at vertebrate animals; but I do not see why it should be permissible to "cruelly torture" a slug or worm rather than a rat or mouse, and I think it would be practically impossible to afford legal protection to any but domestic animals.

1389. (*Chairman.*) But supposing that by the skill of the draftsman, and the power of Parliament, that difficulty were overcome, it would appear, I infer from your last answer, as reasonable in itself to protect the rat or even a slug, if the slug were susceptible of the same degree of pain, as to protect a sheep, or an ox, or a horse, would it not?—My meaning is to distinguish between what may be reasonable in sense of morals, and reasonable for matter of statute.

1390. You have read to us the interesting memorandum drawn up by yourself for the Privy Council which contains excellent sentiments with regard to the treatment of some animals; and I understood you, in your last answer, to say that there was no very clear ground why one animal should be subjected to suffering and not another. If then we find that it is possible to overcome technical difficulties which stand in the way, we should have you on our side, should we not, in overcoming them?—Any law which I should think right, as restricting the physiologist in relation to a dog, would, I should think, be theoretically right in the same relation to any other animal.

1391. But when you got very low in the scale of creation you would perhaps as a physiologist doubt whether the same amount of suffering was inflicted by the same proceeding?—I apprehend that Parliament could not proceed on speculations of that kind; but a high authority says that the "beetle which we tread " upon in mortal sufferance feels a pang as great as " when a giant dies."

1392. The object of that particular sentiment is rather to make giants less careful about their corporal sufferings than to say anything whatever about beetles, if I remember the application of it?—But it cuts both ways.

1393. The words are more usually applied in the way in which you apply them, but I think they are not so by the great authority to whom you refer. But reverting to the question, the particular mode in which you have thought that the law, perhaps, might be amended is by leaving cruelty to be dealt with by the judges or the magistrates before whom the case was brought?—Yes; that the Act of 1849 might, if necessary, have statutory interpretation in regard of inflictions of pain for purposes of physiological study.

1394. Supposing any sensible magistrates to be dealing with the case of a highly sensitive animal, they would apply probably one degree of judgment to that animal, whereas if the animal was a jelly fish, or any of the things that border upon the external scale of what we commonly call the animal creation, they would apply a very different degree, would they not?—No doubt; but I am not sure whether they would always be right in their scale.

1395. So that if your mode of dealing with the subject were adopted, namely, an amendment of the statute against cruelty, the statute would become elastic, if it applied to all animals, and the elasticity would be dealt with by the tribunal?—It would be so; but perhaps penal laws are hardly meant to be elastic.

1396. (*Mr. Forster.*) With regard to the experiments which you conducted, they are chiefly, almost entirely, pathological experiments, are they not?—Entirely; I am not aware that there has ever been any severe operation done.

1397. In my minute which I left, I gave an opinion that there ought to be from time to time a report with regard to these experiments. Has there been such a report?—There is the blue book before you, which I have just handed in.

1398. How far does that blue book give a report of the experiments?—So far as experiments are done, they are mentioned in the separate papers there. If you find no experiments mentioned, you may take for granted that no experiments have been done.

1399. On page 49 I see a mention of communicating sheep-pox by inoculation to a number of sheep?—Yes. Similarly in the paper on tubercle, mention is made of experiments.

1400. I suppose I am to understand that you now think it incumbent upon you, in accordance with my minute, which has been adopted by my successor, to make no experiments respecting which you do not give a report?—Experiments are only done in contribution to some particular research; the research is reported, and the experiments, or the substance of them, in connection with it.

1401. Then I am to understand that no experiments are conducted without a report relating to them?—Quite so.

1402. Have you interpreted the minute which I left to mean that any description of the number of the animals operated upon should be inserted?—Certainly not; its words do not tend to any such meaning.

1403. Then what did you understand that it did mean?—I understood it to mean that I should do

Mr. J. Simon, F.R.S.

15 July 1875.

what I have done in my Report No. 3, now lying on the table.

1404. What did you consider it necessary to insert? —Such reports on the researches conducted as would, where experiments have been performed, render their scientific purpose manifest. And I may add that any scientific report, dealing with experimental matter, almost necessarily includes a statement of the number of experiments on which its conclusions are founded.

1405. (*Sir John Karslake.*) And the kind of animals upon which the operations were performed? —Yes.

1406. (*Mr. Forster.*) What advantage do you think has been obtained for sanitary purposes by any of these experiments?—First, as regards the cholera experiments, all the advice that I give to the public about cholera refers to the infectiveness of the discharges; and the infectiveness of the discharges can hardly be said to have been directly tried on any but lower animals.

1407. In what way do you consider that you have obtained information which will be really useful for sanitary purposes?—By improved knowledge of the causes of disease, and thus gradually showing people how best to avoid the diseases which have been under experiment.

1408. (*Chairman.*) That is, you tell the public that if the discharges which proceed from cholera patients are permitted to get to other people, those other people will in all probability have the cholera? —Yes.

1409. And that you have found out by actually testing it upon animals?—That is my belief; but I prefer to rest on the general principle that, in the unanimous belief of followers of medicine, a more exact knowledge of the causes of disease is our hope, our essential hope, of being able to prevent them.

1410. (*Mr. Forster.*) Then your experiments have been rather to increase the range of mere physiological knowledge than experiments in order to guard against a special disease, or to remedy a special evil?—I put the justification on general grounds. In a particular instance I will justify the experiments, if you please. In cholera we believe that experiment has furnished an exact rational basis for the prevention of the disease.

1411. Then I think I must ask you again, in what way have these experiments enabled you to give advice to the Government or to the public to avoid the cholera or to check its spread?—In that case thoroughly.

1412. Will you tell us how they have done so?— By showing us, for instance, with what extreme watchfulness we must keep even the slightest taint of choleraic excrement out of drinking water.

1413. (*Chairman.*) You administered very small doses of choleraic discharges to living animals, and by that administration of very small doses you discovered that the disease was communicated to the animals; is that so?—Yes.

1414. And from thence you have drawn the inference that it is of the utmost importance to the health of the public to prevent even very small doses of that discharge from being communicated to the human frame?—Quite so; and all our practical advice to the public as to how they shall deal with individual cases of cholera when they occur, and the precautions they shall take against the spreading of the disease, refers to that experimental basis.

1415. (*Mr. Forster.*) Independent of this information gained by experiments on living animals, there was some reason to come to that conclusion from observation of attacks of cholera, and the way in which they had appeared to spread from one patient to another, was there not?—I can hardly say that. Till these experiments were performed in Germany, and had been repeated here, I may confess for myself that I did not consider it to be proved that cholera spread in that way. It had been suspected; it was a theory of cholera which began in 1849, in the teaching of Dr. John Snow; and the theory has been converted by experiments into such degree of certainty, as can properly be held to justify the advice of a Government Department.

1416. Then do you consider that without these experiments upon animals either by you or by somebody else you would not have been able to assert as you now think you can assert, with certainty, that an infinitesimal portion of choleraic discharge may, by getting into the water which a man drinks, give him the cholera?—I think the knowledge could not have existed without experiment.

1417. Now, with regard to experiments that have been made under your direction upon animals for the prevention of disease in the lower animals themselves, what cases can you give us?—I have very great difficulty, insuperable difficulty, in explaining the position clearly in popular form, and that is why I preferred to rest upon the general scientific principle. We are going through successive stages of endeavour, and are at present in but an early stage; we are trying to amend and develop our medical knowledge in accordance with rules which have been discovered to work well for all other branches of knowledge, trying to make our knowledge quite precise. In regard of sheep-pox, we have been getting, as you will see in that blue book, exact knowledge of the contagium of the disease. Hitherto, I fully admit, we cannot prevent sheep-pox otherwise than by the quarantine arrangements which we could have practised before those experiments were performed; but as I said, we are going through a progressive work which has many stages, and are now getting more precise knowledge of the contagium. By these experiments on sheep it has been made quite clear that the contagium of sheep-pox is something of which the habits can be studied, as the habits of a fern or a moss can be studied; and we look forward to opportunities of thus studying the contagium outside the body which it infects. This is not a thing to be done in a day, nor perhaps in 10 years, but must extend over a long period of time. Dr. Klein's present paper represents one very important stage of a vast special study. He gives the identification of the contagium as something which he has studied to the end in the infected body, and which can now in a future stage be studied outside the body.

1418. But up to this time have any of your experiments led to a result which would enable a veterinary surgeon to treat sheep-pox with more hope of cure than he did before?—No.

1419. But you hope that they will do so?—Yes, or rather with (especially) more hope of prevention.

1420. Now, as regards consumption, do you consider that there has been any practical advantage in your experiments with regard to consumption?—We have gained very great advance in knowledge. I again rest on the general position, warranted by all scientific analogy, that with such advance in knowledge we shall necessarily get results in practice.

1421. I am well aware that in medicine as in other sciences, perhaps more than in any other science, the increase of knowlege is most desirable, because from it may come practical advantage; but it is no proof that you ought not to endeavour to obtain that knowledge that up to this time you have not arrived at practical result; but it would be very important to know if practical result has been obtained. Has any practical result been obtained with regard to consumption in the same way as with regard to cholera you have shown that there has been a practical result?—We have gained the knowledge of the communicability of the disease from subject to subject.

1422. (*Mr. Hutton.*) Do you mean by contagion? —By certain ways of contagion; and that will of course have a very great influence in the advice to be given in reference to the disease; but to speak of that as an immediately practical result is, perhaps, not putting it quite correctly.

1423. (*Chairman.*) I understand that you now find that keeping two sheep together you can get tubercular disease in one that was sound before; is that so?—What we know of it is that it is inoculable from subject to subject.

1424. (*Mr. Forster.*) Would what you have arrived

Mr. J. Simon, F.R.S.

15 July 1875.

at induce you to form any opinion one way or the other as to the danger of a healthy person being in close communication with a consumptive person?—It would undoubtedly do so; and I will ask you to observe the particular emphasis which experiments of that sort give to a passage, which I will read from page 7 of the blue book already referred to:—"In "connection with these experiments it deserves "notice that within the last few weeks Dr. Hermann "Weber has brought before the Clinical Society some "facts of a strikingly suggestive kind as to the "possibility of tubercular infection being freely com- "municated to women through their conjugal rela- "tions with men who have pulmonary phthisis in a "quiescent or very chronic state." Dr. Weber had brought before the society several cases of men who, within his own knowledge, marrying in succession two, three, even four healthy women, with no family predisposition to phthisis, had had each wife in turn die of the disease; and the man in each of these cases had apparently from the first been tubercular. The experimental inquiry has opened an immense field, a field of which it is impossible to see the eventual outcome, in the direction of preventive medicine.

1425. You are engaged now in investigations with regard to scarlet fever, are you not?—Yes.

1426. Are you making experiments upon animals in those investigations?—No.

1427. Why?—We have no reason to believe that scarlet fever is communicable to them.

1428. Does the fact that you are not able to make such experiments impede you in the investigation? —It might be a great advantage to us in the study of the disease if we could communicate it to the lower animals, so as to watch its earlier processes.

1429. And your object in making these investigations, I understand, is not merely to acquire knowledge but with the hope of acquiring such knowledge as would enable you, as their medical officer, to advise the Government how to prevent the spread of such a disease as scarlet fever?—Certainly; my opinion being, that scientific advice concerning prevention must in all cases refer to exact knowledge of causes.

1430. As regards these experiments it is your habit, is it not, to put the animal out of the pain of a lingering disease as soon as you possibly can?—Yes.

1431. (*Sir John Karslake.*) Is there much pain attendant upon the disease which you call sheep-pox? —I think it would be fair to assume that there may be.

1432. Are animals, to which you have communicated the disease, curable, or do you generally kill them?—The inoculated disease is usually mild.

1433. Then does the animal recover?—The animal would usually recover.

1434. So that its life would not be sacrificed?—Its life would not necessarily be sacrificed.

1435. But there would be temporary inconvenience and distress caused to the animal?—Yes.

1436. That would be the extent of it?—That would be generally the extent of it.

1437. I understood you to say that in your judgment severe surgical operations by way of experiment are rare at the present time. I think you were referring to Majendie and his times, and saying that as compared with those times they were rare now?—My own work of late years has not been at all in those directions, so that I speak with reserve. I think that you probably would be better informed on that subject by such a man as Dr. Sanderson. I believe that severe surgical operations for purposes of experiment are comparatively rare, and that, if done, they would be done under chloroform. I think that they probably form a very small proportion of the experiments which are done.

1438. Now, may I ask you, as an officer of the Government, have you had occasion to perform any severe surgical operations with a view to establishing any particular fact?—Never.

1439. That has not fallen within your province at all?—Not at all.

1440. (*Mr. Erichsen.*) There is another side of your professional career which has scarcely been adverted to, and it is this, that you are surgeon to St. Thomas's Hospital, and have been so for a great number of years?—Yes.

1441. And your attention has been greatly attracted to the science and progress of modern surgery during that period?—Yes.

1442. Would you tell me whether you think that experimentation on living animals has tended in any way to the progress of surgery during, say, the last half century?—I should say immeasurably. The Commission, of course, knows that medicine is essentially an experimental science, and we save ourselves from a great deal of needless experimentation on man by some experimentations on the lower animals.

1443. I would ask whether the elucidation of such subjects as the process of inflammation, and the repair of a wound in the lower animals, has tended to the advance of surgical science and practice in man, in your opinion?—So importantly, in my opinion, has such been its tendency, that in such questions as those referred to—our knowledge of inflammation and of fever, I myself habitually refer more to what has been learnt by experiment than to what has been learnt in any other way. We cannot get such intricate studies worked out with sufficient exactness in the human subject, though we give all conceivable attention to clinical work, and we are still constantly obliged to fill up the gaps, and to get supplementary means of clinical interpretation, from experiments on the lower animals.

1444. I suppose one may say that surgery is based, not only on clinical observation and pathological research, but also on physiological or pathological experimentation?—Yes; certainly.

1445. And that it has a triple basis in that way?—Certainly.

1446. There is another subject on which there has been some difference of opinion expressed before the Commission, and I should be glad to have your opinion on that point; it is with regard to experiments made on the ligatures of the arteries in animals, the experiments, for instance, that were made by Mr. Jones in the early part of this century, whether those experiments did or did not at the time that they were made tend greatly to advance surgical practice in connexion with the ligature of arteries?—I can only say that when I was a medical student, and our then professor of surgery, my master, Mr. Green, was lecturing on the surgery of arteries, Mr. Jones's experiments formed a basis from which he proceeded.

1447. And they formed the basis on which the practice of surgery has been founded ever since?—Yes.

1448. May I ask you if, antecedently to those experiments, even so great a master of his art as John Hunter erred in the method of the application of the ligature?—Undoubtedly.

1449. And lost patients in consequence of what we now know to be the erroneous method of applying them?—Undoubtedly.

1450. At St. Thomas's Hospital, with which you have been so long connected, there is a large medical school?—Yes.

1451. Is it there the custom to your knowledge of students, I mean of the young men, to be allowed to perform or to practice without permission, experiments on the living animal?—Not to my knowledge.

1452. Or to your belief?—Not to my belief.

1453. You have been connected with that hospital for something like 30 years, have you not?—I went there as a boy in a jacket 42 years ago, and have not left it since, except for an interval of connexion with the medical school at King's College.

1454. And it would certainly have come to your knowledge somehow or other during that period if such were the case?—I cannot conceive otherwise; and at this opportunity I would beg leave to make a collateral observation. I observe a great deal of distinction drawn between experiments which are

Mr. J. Simon, F.R.S.

15 July 1875.

justifiable for one's own study, and experiments which are made for purposes of teaching; and this distinction is intimately connected with the questions which you are asking me. An essential difference between the scientific and the clerical professions is, that the scientific professions have to rest on actual sensible experience; education in them must be a matter of sense; a man must see, hear, smell, touch, handle for himself. When we are teaching our pupils, the universal rule which we have to give them, is that in all matters of sense they must as far as possible use their own senses. Now when that is applied to the matter of physiology, how is the lecturer to proceed with his pupils? Is he to say to them, "Such "and such is the action of the heart; go and verify "what I tell you, each of you separately for himself; "you 300, each of you, go and make this observation "on a frog?" or is he, once for all, to show it to the 300? Is one frog to do for the class, or is each member of the class to take a frog for himself? A physiological teacher (and this goes back to your question) could not fitly discourage his students in seeking under reasonable limits to see things for themselves; but experiments, in any considerable sense of the word, would certainly not be done, except under the direction, guidance, and sanction of the physiological teacher; and a single experiment shown by the teacher to his class may in some cases satisfy the requirements of study as fully as if the 300 students had experimented separately.

1455. Do you think it would be proper to exhibit to the class experiments, such as you have mentioned, showing the action of the heart if it could be done without pain, as it can be done?—Yes.

1456. By pithing the animal that is to say, or by giving it anæsthetics?—Yes.

1457. That the student would learn from such an experiment a vast deal that no description could possibly convey to him?—Yes.

1458. Or another experiment, such as showing the vermicular motion of the intestines, which can be shown in an animal that is dead, that has been pithed?—Yes; but I am anxious not all to underrate the real fact that the life of the animal is sacrificed for physiology; and I think that in discussing these things it is well to use the larger term, and frankly to accept as our responsibility that physiology does involve a limited sacrifice of animal life. Society at large uses animal life for its convenience; it does this to an extent so enormous that imagination cannot reach the dimensions of the use; and in this general use of animal life, the part which physiology plays is a fraction incalculably small.

1459. And many of the most eminent surgeons of the past half century have been in the habit, in order to elucidate certain points, of experimenting upon animals; such men as Sir Benjamin Brodie, Sir Astley Cooper, Mr. Travers, and numerous others?—Yes; and if occasionally there has been an instance of a surgeon who has done no such experiments, he, probably to a larger extent than others, has been an experimenter on his patients.

1460. Is such a man in your opinion greatly indebted for what he knows of science and the practice of surgery to the experiments of others?—Very greatly.

1461. Although he may not practice experiments himself, yet had these experiments not been done by others his knowledge would be of a very much lower standard than it is at present?—Very much so.

1462. In connexion with this subject you would say that physiologists, and occasionally experimenters, do not seek always to establish a new method of treatment or a new operation, but that they lay down a basis, or that they discover facts on which such new methods may afterwards be founded?—Clearly.

1463. (*Mr. Hutton.*) You entirely differ from an eminent witness we had on the theory of poisons yesterday, Dr. Taylor, who gave us the strongest possible evidence that he never found it necessary to exhibit the action of a poison on the living animal, and who stated that by the use of painted wax and various other models, he found it possible to give a complete idea of what was necessary for his students without exhibiting experiments at all on the living animals. You differ from that entirely, I infer?—He would be a perfectly competent witness on that branch of the subject. If he found that method of teaching sufficient for his students I have nothing to say against it.

1464. And as regards the heart, is it not possible to have an artificial heart which pulsates in precisely the same way as the human heart, and exhibits the same phenomena; indeed I have read an account of that in this very handbook before us?—You can imitate the action of the heart to some extent, but not, I think, in a way which would render it undesirable that the student should see an actual heart in action.

1465. As regards pyæmia have those experiments yielded much scientific result?—Yes. I shall very shortly be publishing some results on that subject.

1466. Experiments in pyæmia on the living animal I suppose are of a very painful character; I mean of very long duration?—The cases where the effects are most painful are cases of quickest operation, and the duration of the pain is shortest.

1467. The experiments are of very long duration, are they not?—In what sense "very long?"

1468. You have to keep the animal during the disease for a very long period, have you not?—In cases which are most typical the period would be reckoned in hours; but where the disease produced is of long duration you may take for granted that it is of low intensity, and consequently is less and less the cause of severe suffering to the animal.

1469. But you think that those experiments have yielded clear scientific results; do you mean therapeutic results, or only scientific results?—Scientific results in the most intimate relation to practice.

1470. Typhoid fever is a very bad kind of suffering, is it not, and yet it lasts five or six weeks?—It cannot be said that typhoid fever involves a severe pain of five or six weeks duration; but we have not artificially produced typhoid fever.

1471. That is a kind of blood poisoning, is it not?—That is one variety.

1472. May I ask whom you have employed chiefly for the purpose of these scientific inquiries; as I understand you, you have conducted no investigations yourself?—With the exception of some experiments on the inoculation of tubercle, which I did in 1866 or 1867, I have not for a long while done any experiment with my own hand.

1473. Whom have you chiefly employed in these experiments?—Dr. Sanderson has been at the head of that branch of the investigations which sometimes includes experiments on animals. But it should be understood that experiments only form part of this branch of the work.

1474. Anyone else?—Under him Dr. Klein, and Dr. Creighton, and Dr. Baxter. Now the mention of these investigators reminds me to refer to certain disinfection experiments which one of them (Dr. Baxter) has been carrying on in relation to particular morbid poisons. We were without exact material for advising the public on the relative value of different disinfectants, as means of neutralising the contagia of diseases. He has been doing exact experiments on the contagia of several diseases—on that of vaccinia, that of glanders, that of pyæmia, and that of common putrid infection. He has been making experiments on those contagia with various disinfectants, and getting very precise knowledge which will be the basis of advice which our department will be giving, probably for years to come, on this subject; and I need not tell you how important it is that we should have quite exact knowledge, such as he has been getting.

1475. With regard to the effect on the gentlemen whom you have employed in this large practice of experiments, do you think it has produced no hardening effect at all with regard to their sympathies with the lower animals?—I think not.

1476. You do not think that the habit of regarding

Mr. J. Simon, F.R.S.

15 July 1875.

animals as a mere battery of vital forces on which particular results are to be studied, necessarily to a certain extent produces the effect of diminishing the sympathy with their sufferings?—I think not. I do not anywhere know a kinder person than Dr. Sanderson.

1477. Or than Dr. Klein, for instance?—I have no reason to think otherwise of him.

1478. You were saying, I think, that, as compared with the time of Majendie, this painful class of experiments has diminished in number?—I think so, but have no materials for exact comparison.

1479. You were then comparing, were you not, the state of experiments in France at that period with the state of experiments in England at this period?—I hardly meant to compare the two countries.

1480. Would you say that, as compared with the same period as regards England, this class of experiment has not very much increased. Comparing, for instance, the period of Sir Charles Bell's experiments with this period, would you not say that this class of experiments has very much increased since then?—I should doubt whether any man now does severely painful operations on as large a scale as Herbert Mayo did in those days.

1481. You do not think that this handbook of Dr. Sanderson's gives us a much larger number of experiments of that class than were before suggested as necessary for physiological students?—That book is an encyclopædia of all approved methods of procedure for persons who may wish to do particular observations and experiments on the animal body, living and dead. Instructions as to all are brought together there; but it must not be supposed that each physiologist who consults the book does each of the observations and experiments. Immeasurably the largest use of the book in this country is, I believe, with regard to methods of anatomical preparation from the dead body; and the parts of it which describe severely painful operations which may be practised for particular purposes on living animals would, I believe, be used by but an extremely small number of persons, each of whom again would probably have but an extremely small sphere of experimentation.

1482. A considerable number of these experiments in the handbook are what you call pathological experiments induced surgically, for instance, such as biliary fistula, and diseases of that kind artificially produced. Now are not those a most uncertain and most unnecessary class of experiments, which lead to results which you cannot rely on as being at all like the results which would have followed the natural disease?—I have not myself much experience in those operations; but I feel sure that, so far as they are open to fallacy) which sometimes to some extent they are) those who do them are taking all the pains they can to guard against sources of fallacy, and to improve their methods of procedure.

1483. I have noticed the expression several times in your evidence "within limits." I did not quite understand that you really put any limits on this class of experiments, except, of course, that where pain can be avoided, it should be avoided; but beyond that do you put any limit at all on these experiments on living animals?—It is a question of proportion. I should, myself, not hesitate to sanction the infliction of a great deal of pain on an animal for a very great result; but I should not justify the infliction of the same amount of pain for a trumpery result.

1484. But as you never can tell what your result may be, would you justify the infliction of a very great amount of pain for a scientific purpose without knowing what your result will be?—If you knew what your result would be, your proceeding would hardly be an experiment.

1485. I mean to say without a very clear anticipation of what your result would be. Would you regard this practically, as you regard chemistry, as a science of experiment in which you must not take account of the pain, except where you can prevent it?—I think a great deal must be left to the individual conscience.

1486. And the conscience of the most zealous man of science would, of course, be more callous on that subject than the conscience of a humane person who was less interested in science?—The scientific conscience is subject to correction by comparison with other consciences. There is a great deal of our common life that has to be governed in that way; a great deal, in respect of which the conduct of persons cannot be governed by statute.

1487. And therefore you would not object, perhaps, to bring in the conscience of the public as a modifying influence in relation to these men of science?—Of the thoroughly educated public, not in the least; of the mob, very much.

1488. Then would you object to limiting these kinds of experiments to special places and special persons, and to subjecting them to inspection?—It would be a sham security, I think, as compared with that which already exists.

1489. But if not a sham security, you would not object to it?—On the contrary, if it were so constructed as to be a real security, it would probably interfere with work to a degree that would oblige workers to take refuge in other countries.

1490. But that would depend surely on the certainty that a thoroughly scientific man would have of obtaining a licence?—Legislation such as you suggest might be proper, no doubt, if it were shown that there already existed any great wrong; but I dispute the existence of such wrong.

1491. Do not you admit that on the Continent, certainly in Italy, and probably elsewhere, these experiments have been pursued in a very reckless spirit?—I do not know enough of what has gone on in Italy to speak positively about it; but I can speak with comparative positiveness of what goes on in this country, and my belief is that, according to our received ethics, there is not any such wrong in this country. I say "according to our received ethics," because you must take this question of physiology with the general social context; and I do this as impartially as I can when I think of projects of legislation in the present matter. I take up, for instance, one of these Bills, and I find this: "Whereas it is "expedient to prevent cruelty and abuse in the "*experiments made on living animals for the purpose* "*of promoting discoveries in the sciences of medicine,* "*surgery, anatomy, and physiology.*" Now suppose this preamble to be before either of the Houses of Parliament,—I speak, of course, with great respect to those Houses,—do you suppose that one of Magendie's experiments, the worst of them, is more cruel to the sufferer of it than hare-hunting to the individual hare, or fox-hunting to the individual fox? And is animal life less to be protected against "cruelty" when the life is sacrificed for purposes of sport than when it is sacrificed for purposes of science? You are proposing that physiologists shall be treated as a dangerous class, that they shall be licensed and regulated like publicans and prostitutes: what I would venture to put before you is, that this would be fancy-legislation, touching the relations of man to the lower animals at a little bit, and a comparatively unimportant little bit, of the subject-matter; and that society would come to such legislation with unclean hands. Who is the accuser of the physiologists? Society assumes an universal right to slaughter animals for its food, to cut their throats or wring their necks at its discretion, and neither stints its luxury (much less its hunger) in reluctance to take life, nor troubles itself much about painless methods of killing. To kill particular animals in particular ways is a considerable branch of national amusement, and the wealthy breed certain animals on a large scale exclusively to have sport in killing them, and for the unpractised often to mangle where they do not kill. Also with a view to slaughter, or with a view to other service, society inflicts sexual mutilation on nearly all the males of the cattle, horses, sheep, and swine, which it controls, Mr. J. Simon, F.R.S.

15 July 1875.

and, as to swine, on many of the females. You never eat a mutton chop that does not come from an emasculated sheep: you rarely use a male horse that has not had its testicles cut out. Now when the common habit of society treats domestic animals in this way, slaughtering and mutilating them at its will, for use, for convenience, for luxury, and while battues and wager-slaughtering and hare-hunting are elements of national sport, it seems altogether monstrous to put into a separate category the extremely small use which physiology (for great human interests) makes of the lives of brute animals, and to have as the preamble of a Bill that cruelty is to be prevented in that one relation while all the other relations are to be left loose.

1492. Are you aware that in this handbook a very large variety of experiments on frogs, and of very painful experiments, are contained, in very many of which nothing which has any of the effects of an anæsthetic is used except curare, which is not an anæsthetic; and do not you think that the effect of those kinds of experiments on medical schools is to diminish the sympathy of men with the lower animals? You see this Commission is not occupied with sporting, or we might have something to say about that; it seems to me that we have no business to go into that subject?—Questions put to me have regarded the propriety of submitting physiology to a system of licences and inspections. It was in reference to that that I spoke.

1493. If we had to consider the subject of sporting I might have something to say upon that; but surely in relation to the healing art it is of the greatest possible importance that habits of cruelty should not be in any way encouraged. Now we have a new school of teaching which puts before the public a large variety of experiments, some of them very painful experiments, as a discipline through which the physiological students ought to be passed. It seems to me a fair question to ask you whether you do not think that a dangerous school to put them to?—Instead of answering that *à priori*, I would answer, as matter of observation, that doctors who have passed through these studies are certainly not unfeeling people.

1494. I should think that was a very questionable thing with reference to the Continent. I have heard a great deal of evidence to the effect that, especially in Germany and Italy, a great deal of the hospital practice is cruel in consequence of the schools through which the medical men have passed. At all events, surely you will not deny that if a great variety of painful experiments are recommended to young medical men, that is a dangerous school to which to put them?—I am not aware, as matter of fact, that such experimental physiology is recommended as a study for all medical students.

1495. No; but for the higher class, I suppose?—Certainly not such experiments as I believe you to refer to: but probably sometimes an advanced medical student individually uses a living frog for an observation which causes it pain.

1496. Are you aware that a class of frogs is imported from Germany for the express purpose of these experiments, the English frog being not so able to bear the pain of them?—I have heard it stated that for some physiological uses foreign frogs are preferred to English.

1497. Does not that fact itself imply that a considerable number of very painful experiments on frogs are now made before our physiological students; and are you prepared to say that that is in itself a good school for physiological students?—Where such experiments are performed, it is by the masters, not by the pupils in physiology, and gives perhaps to a large class of the latter (as I before explained) some very desirable opportunity of personal observation which otherwise each could only get by separate experiment done for himself. I see no reason why this should be of bad influence, unless the method of teaching were abused.

1498. I do not say that a large number of frogs is used at haphazard, but Dr. Michael Foster in this handbook speaks of the frog as being the chief subject of physiological experiments; and what strikes me as most remarkable is that it is the frog which is least frequently given an anæsthetic. You say that the number of experiments performed under anæsthetics is very much larger than that of those not so performed; it strikes me that there is evidence of the other kind in this handbook?—I had throughout been speaking particularly with reference to domestic animals.

1499. Still we have no reason to believe that frogs suffer materially less than the domestic animals, have we?—I have difficulty in comparing the two, but of course have no doubt as to the frog's full susceptibility of pain.

1500. Still if it be a fact that although anæsthetics are given to a number of domestic animals they can with difficulty be applied to frogs, surely the number of the physiological experiments in this handbook, to which frogs are subjected, is a very dangerous discipline to which to submit young men? Would you not admit as much as that?—If it were recklessly done, yes: but I think that you misapprehend (as I before explained) the meaning of the handbook, and that you regard it as prescribing a common curriculum for students, where it is in reality only an encyclopædia of reference for experts.

1501. Then you would have no objection, if there were any fear of that, to a certain amount of control and restriction?—I should have a very strong objection. If there be evil, I think that would not be an available way of dealing with it. It is a matter, I think, within the province of conscience, and not one to be managed by legislation; I cannot conceive that there could be legislation for the protection of frogs. I think that none of the physiologists I know would recklessly hurt even frogs. I admit that, taking all physiologists together, there is a good deal of hurting of frogs; but the gain to physiological science is very great; and, according to our common estimate of the relation of man to brute, the importance of the result to mankind justifies the sacrifice of the brute.

1502. And that as a rule they find it exceedingly difficult to give a real anæsthetic to frogs?—Yes; but again I would say *respice finem*. It is done for a purpose, and it must be considered with reference to the purpose; and it must be considered, I again venture to say, with the general social context. The special case cannot be fairly considered without reference to the whole treatment of the lower animals by man. In regard of "severely painful operations," let me again particularly refer to the many hundreds of thousands (probably some millions) of castrations which are annually done on domestic animals, as part of the ordinary routine of farm management;—vivisections, in comparison with which all which physiology performs are as nothing. And for that vast system of popular vivisections, what justification can be pleaded except that man thinks it for his advantage?

1503. (*Chairman.*) I think you just now, in answer to some questions that I put to you, intimated that it might be proper under certain circumstances to strengthen the general law with regard to cruelty to animals, and to extend that law to other animals which are not now included within it. That was a different kind of legislation from that about which you have last been asked. You have understood I suppose that the last questions pointed to regulation of a special character, like giving licences, and inspections, and so forth; but you did not intend to withdraw the answer that you have previously given on the general subject?—No.

1504. Now, with regard to this particular preamble which you just now quoted with objection, that is found, is it not, in a Bill introduced by Dr. Lyon Playfair in the House of Commons?—Yes.

1505. You probably have the same information that we have about that Bill, namely, that it emanated in a considerable degree from some of the most eminent names in physiological science in this country?—I am aware that several most eminent persons in science

Mr. J. Simon, F.R.S.

15 July 1875.

had some concern in it; I do not know exactly what concern; but I presume not to the extent of being responsible for it in all parts.

1506. You are aware that the preamble is not the operative part of a Bill?—I am.

1507. And if, therefore, any particular objections were taken to the preamble, that, probably, might easily be accommodated?—Yes; but when I argue against the preamble, it is not as against something which shall be in print, but as against something which is the mental premiss from which these proposals start.

1508. Therefore, it is not an argument against a Bill, really prepared by eminent physiologists, that those particular words might bear a disagreeable interpretation?—No; but I think, perhaps, the eminent physiologists may not quite have considered what the actual operation of this, if it became law, would be.

1509. I think you expressed the opinion that it would not be an efficient security?—I think it would not be a security for animals, and I think it would give facilities for the persecution of physiologists. I think that physiologists under law of this sort would in these days run some risk of being treated as Vesalius was three centuries ago. The Commission will at once recognize how easy it would be, if this Bill were law, for some one to move in Parliament for a return, under section 5 of clause 3, with regard to all experiments which had been made; that is to say, to convert the law into means of popular attack on individual physiologists.

1510. (*Mr. Hutton.*) It would be possible to refuse that return?—It would perhaps be possible, but probably difficult, to refuse it. I should be very unwilling, I confess, to see physiologists put in a position in which those who are now making clamour on these subjects should be able to hold them up individually to popular odium; and under this clause that could be done.

1511. (*Mr. Forster.*) With regard to the investigations conducted by you and your assistants under the Parliamentary vote, I gather from your answers that there are positive instructions that there should be no operation on any living animal without anæsthetics?—On receiving your minute I immediately communicated it to Dr. Sanderson, with a request that he would "please read, and note as an instruction, the above minute by Mr. Forster;" and Dr. Sanderson returned me the paper as "read and noted." I should like to bring if I may under notice of the Commission that 30 years ago discussion was going on such as has been going on lately about vivisection, and that at that time there was written a pamphlet, I believe under pseudonym, entitled "Remarks on the use of "Vivisection as a means of Scientific Research, in a "letter addressed to the Earl of Carnarvon, President "of the Society for Preventing Cruelty to Animals, "by Richard Jameson;" and that this pamphlet goes through much of the matter which the Commission is now considering. It is so thoughtfully, and I think justly written, that if it is not out of print, I would suggest that the Commission might like to see it.

1512. (*Chairman.*) You say it is under a pseudonym?—I believe it to be so.

1513. You are not at liberty to say who the author is?—I am not at liberty to mention my suspicion of the authorship.

1514. (*Sir John Karslake.*) Do you believe him to be a man of eminence?—Yes.

The witness withdrew.

Adjourned.

Tuesday, 19th October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

Mr. JOHN COLAM called in and examined.

Mr. J. Colam.

19 Oct. 1875.

1515. (*Chairman.*) You are the Secretary of the Royal Society for the Prevention of Cruelty to Animals?—I am.

1516. How long have you been so?—Fifteen years.

1517. During that time I presume it has been your province to carry into execution the wishes of the society, as far as you could, in reference to the subject which we are appointed to consider?—Yes.

1518. Has that given you the means of knowing, with any considerable degree of accuracy, what is the actual practice in this country on the subject. Do you know, that is to say, what things are done to animals habitually in this country?—Personally, I know a little, and from reading, I think I know a little more.

1519. And can you inform us what is the actual state of things now in existence in this country?—Vivisection is practised of course, and very often with very much pain to the animals; that is undoubted.

1520. Have the society arrived at so much of a conclusion on the subject as to be enabled to put their wishes into the form of a Bill?—They have.

1521. Have you got that Bill with you?—I have.

1522. Are you prepared to give it to the Commissioners?—Yes (*handing it in*).*

1523. Will you tell us, if you please, in general terms, what the provisions of that Bill are?—The main feature is that it prohibits all painful experiments.

1524. By "painful experiments," will you tell us what exactly you mean; is an experiment in its nature painful within the prohibition of your Bill when performed under complete anæsthesia?—The experiment is without pain then.

1525. Then it would not fall within the provisions of your Bill?—Certainly not.

1526. Will you tell us in general terms what the Bill provides?—With regard to that question of inflicting pain, the ninth section provides: "That no "person shall perform, or cause to be performed, or "take part in performing, any vivisection upon any "animal, without having first of all subjected such "animal to the influence of an anæsthetic, so as to "render it wholly insensible to pain;" and then the next section provides: "That no person who shall "perform, or cause to be performed, or take part in "performing, any vivisection upon an animal so subjected as aforesaid, shall omit to destroy such animal, "before the effect of the anæsthetic ceases."

1527. Then you seek entirely to prohibit the infliction of any pain upon any animal for the purposes of scientific investigation or discovery?—Yes, that is so.

1528. Now suppose the case to be this: that an

---

* Appendix III., § 5.

Mr. J. Colam.

19 Oct. 1875.

experiment is performed under an anæsthetic, and the actual operation is not therefore painful to the animal, but suppose the recovery from that operation to involve some pain; that would be an operation prohibited by your Bill, or your Bill would require that the animal should be destroyed?—Undoubtedly.

1529. So that if an experiment were tried for the purpose, for instance, of improving the mode of tying arteries, and the principal pain were removed by an anæsthetic, it would be contrary to your Bill if the animal were allowed to recover afterwards, and there were some pain in the process of recovery?—Yes, I think it would be, because it provides that the animal must be rendered "wholly insensible to pain," and that the animal must be destroyed while anæsthesia remains. But I would like to add, that very frequently the pain is quite as severe after the ligature has been made as it is at the time of the operation.

1530. Now as regards the practice, so far as you are aware of it at the present time, are experiments performed in which no anæsthetic is used?—Undoubtedly.

1531. And experiments in which an anæsthetic might be employed without prejudice to the supposed object of the experiment?—Upon the opinion of others I should say so; but as a layman I am scarcely able to answer that question.

1532. But that is the conclusion at which, as the secretary of the society, you have arrived?—Quite so.

1533. Will you give us some instances which, in your opinion, best illustrate what is actually done?—I have here a mass of evidence consisting of 370 pages, which has been culled from various books reporting experiments, in which there is evidence of pain. I have also other quotations in which there is evidence of prolonged pain. With regard to the question put to me, of course it would be impossible for me to go through this large number of cases. I will just name one or two. It does seem to me that there was a great deal of pain caused by the suffocation of dogs when a number of animals were drowned and half drowned and again restored to life and then drowned again by a Committee of the Royal Medical and Chirurgical Society in consequence of an application by the Royal Humane Society to them to consider some better means for the resuscitation of persons apparently drowned. The experiments which are recorded here will show you that the animals were, several of them, two or three times put into water half drowned, and kept in water three, four, or five minutes, and then brought again to life, and thus put to horrible agony. It might be said that the object was very good, but the answer to that is that the cruelty was really fruitless, as the report admits that no conclusion could be drawn from the experiments. The report shows that experiments on dead human bodies were useful. Practically, Dr. Sylvester's method was recommended by the committee appointed by the Medical and Chirurgical Society, which method was in use before the inquiry took place, and is still in use. I wish to add that the Royal Humane Society is not at all responsible for these experiments.

1534. I understand you that you have there 370 pages of evidence, from the length of which you wish us to take them as read without putting you to the task of reading them through. Did I rightly understand you to say so?—Yes, I put them in for your perusal.

1535. Have you got the references and the names specified?—In every case.

1536. Will you be so good then as to put in the references to those instances, and the authority upon which in each case your statement rests?—I will.

1537. (*Sir John Karslake.*) I understand that these are extracts written out by yourself from different books?—Yes, or by my orders; altogether about 800 pages of foolscap.

1538. (*Chairman.*) Will you at the present moment make a selection of a few instances which you think will best inform the Commission of the points which you desire to bring before them?—I am scarcely prepared to analyse, because I thought that I should just simply have to put my evidence in for your perusal; and, therefore, the analysis consists of divisions in this form:—evidence of painful experiments, evidence of pain prolonged, evidence of design to teach students vivisection in laboratories, and evidence of vivisection performed by students themselves (which I have only found one instance of in the whole of my inquiry), and opinions in favour of restriction, and against vivisection.

1539. You said, I think, that some of the experiments you have collected were instances of protracted agony?—Yes.

1540. So far as you know had any attempts been made to use anæsthetics in those cases?—I believe not. In some cases it may be that it would defeat the object of the experiment if an anæsthetic were used.

1541. But as a matter of fact where there has been an experiment involving what you have called protracted agony, is there any reason to suppose that it has either been possible, or that at any rate it has been the fact that agony has been counteracted by chloroform or other anæsthetic?—No.

1542. In that case it would defeat the object of the experiment to use an anæsthetic?—Yes, generally, I think.

1543. In the cases in which it would have been possible so far as time or the object was concerned, do you consider that anæsthetics have been used always?—I believe that generally the English physiologists have used anæsthetics where they think they can do so with safety to the experiment.

1544. Then may the Commission take your belief to be that there is a desire on the part of the scientific men in this country so far to get rid of the infliction of pain as is compatible with the scientific object which they have in view?—I should say so, generally, but in some cases there appeared to be some heedlessness with regard to the suffering of the animal; for instance, in some of Brown Séquard's experiments, where animals were kept for weeks in suffering.

1545. May I take it to be your view that the general tendency of the English scientific world is not at variance with humanity?—I believe it is very different indeed from the practice of foreign physiologists.

1546. So that you would treat cases of wilful cruelty, if they exist at all in this country, as exceptional cases rather than as fairly chargeable upon any want of proper sentiment on the part of the profession?—Undoubtedly with regard to wanton cruelty. I do not know that I know of a single case of wanton cruelty, by which I mean suffering caused without any object except to gratify a cruel mind.

1547. Then you give the scientific men of this country credit for using anæsthesics, and dealing tenderly with animals so far as is compatible with the objects which they have in view?—Yes; I think so, speaking generally. As regards tenderness, I have no evidence to prove they are tender to animals.

1548. That the cases where that is not so are exceptional cases, and not cases fairly chargeable to the profession generally?—I think so.

1549. But you think that experiments are performed which are in their nature beyond any legitimate province of science, and that the pain which they inflict, is pain which is not justifiable to inflict, even for the scientific object which they have in view?—That is the opinion of our society.

1550. Now with regard to students, have you any evidence that you can lay before us as to what is done in respect of students?—With regard to London I have inquired at every school, and I have not found a single place where experiments are actually performed before students. The animal is operated on in the laboratory and brought out thence in a narcotised condition, and then it is examined by the students.

1551. Do I rightly understand you to draw a broad distinction between an experiment performed for the purpose of establishing some new scientific truth on the one hand, and on the other hand the repetition of such experiment, after the truth in question has been established, for the purpose of illustrating it to students?—Undoubtedly the society draws a very marked line there. A difficult question, of course, does arise as to when the truth has been fully established, but illustration to students is altogether objected to.

1552. But supposing that the object is to establish some new scientific truth, and that anæsthetics are as much employed as the nature of the case admits of, I still understand you to say that the society object unless the anæsthetics can be so far employed as to take away the pain altogether?—Yes, the society is a society for the prevention of cruelty, and would not step out of its direction to legalise anything contrary to its nature; it would be a misnomer for the society as a corporation to legalise cruelty for any purpose. What individuals in the society might be willing to do would be a different matter.

1553. Do I rightly understand you that there are individuals in the society who maintain a different view, but that the society in its corporate capacity speaks through the four corners of this Bill which you have put in?—Undoubtedly.

1554. Does that include this, that some members of the society would probably go beyond this Bill?—Undoubtedly there are some who would prohibit all experiments, and others who desire that no Bill should be framed, believing the present statute sufficient to suppress cruel experiments.

1555. And there are others who you think might not go so far as this Bill?—Yes, undoubtedly.

1556. But in its corporate capacity the society speaks through this Bill;—Yes.

1557. This Bill was framed after the society had before it the two Bills that were introduced into the two Houses of Parliament last year?—It was; but we had previously drafted two other Bills.

1558. And of the two it is framed more upon that introduced into the House of Commons by Dr. Lyon Playfair than upon the other?—I think so; but certainly it takes some of the provisions of the other Bill.

1559. Now would you have the kindness to state to the Commission what are, in your opinion, the principal differences between the proposals which were made last year to the two Houses of Parliament, and the Bill which on the part of the society you are authorised to submit to us?—The first thing that I note is, that Dr. Lyon Playfair's Bill provided that it should come into operation immediately, and ours provides on the 1st of January. That is perhaps an immaterial matter, but this Bill provides that there shall be no pain inflicted; that is the leading feature of it. Then, too, it asks for power to go to a justice of the peace and get a search warrant if there is reason to think that the law is being infringed.

1560. That provision perhaps is due to some experience that the society may have of the way in which their attempts at prosecution have heretofore been defeated?—Undoubtedly; and especially with regard to this question; for now it is next to impossible for the society to know what is going on actually. Then there is another difference which I should like to point out, which is that there is a more ample provision in this Bill for the registering of experiments, especially with reference to the results of the experiments; the object of the society being two-fold: first, that it might have an opportunity of testing whether the experiments were doing any good, and secondly, that it might by the publication of the results prevent the repetition of experiments; because if those results were published it would undoubtedly prevent much experimentation.

1561. Your main difference from the Bill of Dr. Playfair is that you omit altogether the provision which he made for the infliction of pain in a certain class of experiments?—Just so.

Mr. J. Colam.

19 Oct. 1875.

1562. And you comprehend all painful experiments in the prohibition of your Bill?—Yes.

1563. Then, like Lord Henniker, you adopt the proposal for a license in regard to places?—Yes.

1564. And you extend that to persons?—Yes.

1565. So that if your view were to be adopted by the Legislature no painful experiment could be performed at all?—None.

1566. And no experiment, whether painful or under complete anæsthesia, except by licensed persons in licensed places?—Undoubtedly.

1567. Is there anything that you desire to bring before the Commission which has not been included in the questions already put to you?—I do not know that there is, excepting that the committee are very anxious first of all that you should understand that the Royal Society for the Prevention of Cruelty to Animals is not the society advertised for the total abolition of experiments, and that it is not responsible for the rash literature which has been printed on this subject; and secondly, I was instructed when I came here to read to you what the society have done on this subject, and what the committee, upon the presentation to them of a memorial against vivisection, did in reference to the examination of the allegations of the memorial, and deliberations upon its prayer.

1568. That is a document prepared under the sanction of the society, and you are speaking their language when you read it to us?—Yes. 'To the 'Honourable Royal Commission on Vivisection. 'My Lords and Gentlemen. In response to your 'invitation, the Royal Society for the Prevention of 'Cruelty to Animals have desired me to appear 'before you for the purpose of placing before you 'the evidence they possess in relation to the practice 'of vivisection in this country. Instead of a layman 'they would have preferred that their representative 'should be a medical man or a physiologist, whose 'experience and special education would prove to be 'of more service to you than my information can 'possibly be. There are, however, good reasons to 'prevent the attendance on their behalf of an expert, 'some of which may be found in my better acquaintance with their views, and with the proceedings of 'the society in reference to this practice. They 'have desired me to place myself entirely at your 'service. To this end I have already suggested the 'invitation of several witnesses who may be expected to place information and arguments before 'you. It will be convenient, perhaps, for me to 'state (1.) What course the society have hitherto 'taken against vivisection, and what means they have 'employed to get evidence. (2.) The nature of the 'information they have obtained and propose to place 'in your hands. The practices which they opposed 'many years ago at Alfort and Lyons Veterinary 'Schools, with much success, scarcely come within 'the meaning of the term 'vivisection,' as they 'were designed to teach dexterity of manipulation, 'and were, therefore, more of the nature of operative surgery. As similar practices do not prevail 'in this country, and, on the contrary, are reprobated by physiologists on this side of the channel, 'it will not be necessary to allude further to them. 'Thirteen years ago I was instructed to make an 'inquiry into the practice of vivisection in Great 'Britain, and addressed letters to the schools of 'medicine, asking for information. The committee 'of the society were much gratified to find that at 'such time there was every willingness on the part of 'professors to supply the data asked for, and particularly that there appeared to them to be comparatively few operations being made at such institutions. Nevertheless, it was considered desirable to 'use every possible moral means to check the spread 'of vivisection. The committee, with this view, 'offered prizes for the best essays against that practice, placing two questions before the essayists, as 'follows:—I. Is vivisection necessary or justifiable '(when performed as at certain veterinary schools) 'for the purpose of giving dexterity to the operator?

Mr. J. Colam.

19 Oct. 1875.

'II. Is it necessary or justifiable for the general purposes of science, and if so under what limitation? Assisted by eminent judges the awards were made, and the essays by Mr. Fleming and Dr. Markham were printed, a copy of which I now lay before you. Other and many means were used to the same end. Last year the committee felt bound to institute a prosecution against Dr. Magnan and others at Norwich for alleged cruelty to dogs during an experiment at the meeting of the British Medical Association. The evidence in that cause with a report of its result they put before you on this occasion. Last year also an international congress of societies assembled in London to discuss common objects tending to promote kindness to animals, at which resolutions were unanimously passed by the delegates condemning the growing practice of experimental physiology so far as it tends to animal suffering, and pledging itself to check vivisections in the various nations of Europe and America. Owing to the alleged increase of experiments an influential deputation appeared before the committee last January, and presented a memorial to the society, praying for its active interference to repress vivisections. A copy of that memorial is now handed to you with the names of the principal persons who signed it. A committee of the society was at once formed, charged with the duty of inquiring into the allegations of the memorial and deliberating on its prayer. That committee held frequent and long sittings, and delivered its report to the general committee in due course, the following being the substance thereof. "We have held several meetings and have taken much pains to obtain evidence to verify the allegations made in the memorial as regards the extent to which the practice of vivisection prevails in the United Kingdom, where, by whom, and for what objects, experiments are performed; and whether or not animals experimented on are previously made insensible to pain, and kept during experiments, and until destroyed in a condition of anæsthesia. At every stage of our inquiry we have experienced great difficulty in procuring such evidence. Avenues leading to private laboratories are closed to this society, and private operators whose conduct is under investigation and public stigma have not been found willing to volunteer information. Moreover, the gravity and complexity of the subject call for more than ordinary care and exactness in the collection of reliable data. In the first instance we addressed a circular to the several hospitals, infirmaries, and medical schools of the metropolis, to which places the memorial appeared to refer [a copy of which I hand in to you]. The managers were respectively invited to supply particulars relating to operations on living animals in those institutions, and to permit the secretary to be present on occasions when experiments were being conducted. The following return will show the results obtained by such measure. No replies have been received from St. Thomas's Hospital, West London Hospital, Infirmary for Consumption and Diseases of the Chest, North London Consumptive Hospital, City Orthopœdic Hospital, Harrison Spinal Institution, National Orthopœdic Hospital, Royal Orthopœdic Hospital, Central London Throat and Ear Hospital, Ear Infirmary, Central London Ophthalmic Hospital, Ophthalmic Hospital, St. Peters' Hospital for Stone and Urinary Diseases, Epidemiological Society. Acknowledgments only have been received from the Medical Society of London and King's College Hospital. Evasive answers were received from University College Hospital, St. Mark's Hospital, City Road, and Great Northern Hospital. No experiments are performed at East London Hospital, Royal College of Surgeons, Hospital for Diseases of the Nervous System, Western Ophthalmic Hospital, British Hospital for Diseases of the Skin, London Fever Hospital, Royal College of Physicians, Hospital for Hip Disease in Childhood, Royal Hospital for Diseases of the Chest, National Hospital for the Paralysed and Epileptic, King's College Hospital, London Hospital, Hospital for Consumption and Diseases of the Chest, Royal Dispensary for Diseases of the Ear, City of London Hospital for Diseases of the Chest, Metropolitan Free Hospital, Obstetrical Society of London, German Hospital, Poplar Hospital for Accidents, Female Lock Hospital and Asylum, Male ditto, Royal South London Ophthalmic Hospital, St. Mary's Hospital, St. Saviour's Hospital, Royal Free Hospital, Cancer Hospital, Royal London Ophthalmic Hospital, St. Mark's Hospital, London Infirmary for Diseases of the Legs, and Great Northern Hospital. Vivisections are performed at the Westminster Hospital, Broad Sanctuary, Guy's Hospital, and the Pathological Society. Admission has been refused by the Middlesex Hospital (from medical committee, not board of management), Charing Cross Hospital, Pathological Society of London, Chemical Society of London, and the Royal Medical and Chirurgical Society. The following have consented to admit: Westminster Hospital (qualified persons only), St. Bartholomew's Hospital, Guy's Hospital, the Brown Institution, and St. George's Hospital. Mr. Fleming and the Secretary accepted the invitation to attend at Guy's Hospital, and have reported thereon as follows: 'In compliance with an invitation we visited the above Hospital to-day, when we had an interview with Dr. Steele for the purpose of ascertaining the nature of the experiments performed on animals at the hospital. During our conversation Dr. Steele said: 'I can give you positive assurance that students do not perform any experiments on animals here, for Doctors Pavy and Pye Smith are the only operators on animals. I do not believe there is any cruelty to animals performed in any experiment as anæsthetics are invariably used.' He handed to us the annexed Hospital Report, and upon our calling his attention to a passage marked at page 48 [that passage seemed to imply that there was vivisection performed before students; but it was explained to be rather ungrammatical language], he said it was an unfortunate sentence, and that the secretary of the medical department should have qualified it by adding 'all animals being narcotised.' He said, he was glad to see us for the purpose of correcting wrong impressions, and would admit us to the hospital at any time. He then conducted us to Dr. Pavy's private laboratory, where we saw three living dogs (a long haired terrier, a pug, and a mongrel,) which, we were informed, were shortly to be the subjects of experimentation. We also saw an operator's table, and several appliances for experiments. Dr. Pavy said, during our conversation with him, 'I am glad you have come to my sanctum to judge for yourselves whether we are cruel or not. There is much misrepresentation abroad on this subject, which no doubt arises out of an unfortunate expression coined by the College of Surgeons some time ago, when they desired that students should be taught what they called 'practical physiology.' Students are not, and never have been, permitted to perform experiments at this school, neither do they ever see experiments performed on animals which have not previously been rendered insensible to pain. I will tell you all I do before the students, and privately in this laboratory. Every animal dissected before students is either narcotised or pithed' (an operation on the *medulla oblongata* which destroys life), 'except in the case of frogs, which I decapitate in the presence of the students, and before I commence to operate on them. The chloroform is administered, and the pithing is performed in this laboratory before the animal is taken down into the lecture room for demonstration, and the animal is killed before consciousness returns. I would not dare to perform an experiment before the students upon an animal not previously narcotised, any more than I would

Mr. J. Colam.

19 Oct. 1875.

“‘dare to commit an act of cruelty before your eyes in Jermyn Street. In all my lectures I have always felt that I have not done a single thing, nor said a word I should be afraid of your seeing and hearing, and, indeed, I have felt it my duty to act as though you were present in the room. Could I have been guilty of giving pain to a dog or cat during my lectures, I am sure the students would have been the first to protest against it. I do not use more than 18 animals during my lectures in a term.’ He then showed to us his appliances for administering chloroform and his instrument for pithing dogs, also a book which contains directions to his assistant for the preparation of lectures, in which it is provided that the animals should be pithed or rendered insensible to pain by means of chloroform or puff balls. From this book the lectures given by Dr. Pavy appear to be mostly of a physical nature, and the animals alluded to are shown only to advanced classes. In answer to questions Dr. Pavy said that his private experimentation referred chiefly to the secretions. He said, ‘I invariably use chloroform in all my private experiments, and am convinced after much thought on the subject that, taking the aggregate of experiments required by science to be performed on animals, not one in 500 need cause any pain whatever to the animals, and in those which I perform an anæsthetic may be administered in every case. I have told you that I do not use more than 18 animals per term for my lectures, but I cannot say how many I use in this private laboratory. I have often said here what a boon chloroform is, as it enables us to perform almost any experiment we like upon an animal that does not quiver, or start, or struggle, but allows us to cut away as we require, and does not prevent reliable deductions except in a very few cases. Although I always narcotise an animal, I do not always kill it before sensibility returns, but I nearly always do so. Sometimes it is necessary to keep it alive after the anæsthetic has ceased to act, especially in any researches relating to digestion. On one occasion I produced fistula in an animal’s stomach to study the process of digestion, and kept it alive for such purpose several days, but the dog was as happy as possible, and even sat on my operating table while other dogs were being operated on without any sign of uneasiness. When animals recover from chloroform and are still kept alive in the manner described they suffer no pain. During the cutting process they are narcotised, and after such operation when sensation returns I am convinced they do not suffer pain. Even human patients in our hospitals whose limbs have been amputated while they were under the influence of an anæsthetic feel no pain at the wound upon their return to consciousness. In all possible cases, however, I destroy the animal during its insensibility. I do not believe that students perform experiments on animals as they have no time for laboratory work. Experiments by students would be discountenanced by every teacher at this school. I shall be glad to see you at any time or any person you may send. If your society acts discreetly at the present time in reference to this subject, it may do much good by checking excess in experiments on living animals.’ Dr. Pye Smith also expressed himself as glad that the society was engaged in investigating into the allegations made against experimenters. His lectures were confined mainly to histology.’ He said, ‘I have a summer course, however, when I experiment on animals, but never without chloroform having been previously administered; indeed I perform no experiments without an anæsthetic. I have done many experiments, but I am not aware that I have ever given pain to an animal. I am in favour of students seeing experiments on animals which are at the time insensible to pain. I have not seen anything performed at the Brown Institution of which I disapprove. An anæsthetic agent may in nearly every case be administered to animals before the experiment commences. I am not now attending to the trial of new medicines on animals, which is necessary before giving such drugs to human beings. Alluding to a mistake made by the memorialists respecting experiments on the eyes of animals by students, Dr. Pye Smith admitted that it was a natural error arising out of the construction of the sentence quoted from the report of St. Thomas’s Hospital, which was calculated to mislead. (Signed) George Fleming, John Colam.’ The secretary attended at Saint Bartholomew’s Hospital by invitation of Dr. Lauder Brunton, when he witnessed several experiments on cats and frogs performed by that gentleman in his private laboratory, in all cases the animals having previously been rendered wholly or almost entirely insensible to pain.” [I ought to say that I found Dr. Brunton extremely willing to give me every information, but I cannot believe that in one or two cases the cats which I saw there were entirely without pain, not simply because of their movements, but because of the necessity there appeared to be again and again for him to insert blotting paper into chloroform and put it to the nostrils of the animal in order to lull it when it commenced to cry a little.] “Dr. Brunton stated that such vivisections fairly represented a day’s work, that each would have taken place precisely as then seen had the secretary not been present, and that even if for no higher purpose animals are invariably narcotised in this, and he believed in other laboratories, for the advantage of easier manipulation before the experiment is commenced, and are generally destroyed before sensibility returns.”

1569. (*Mr. Forster.*) Were all the animals destroyed which you saw?—They were. In fact the dose of chloral was so heavy that I have not the slightest doubt they could not have recovered from it. “The object of the experiments which Dr. Brunton was then employing was to ascertain the action on the heart of certain poisons used by the natives of Jamaica and Southern Africa for the destruction of Europeans, and to discover a remedy for the same. Two lectures delivered by Professor Ferrier at the London Institution on the results of his experiments on animals have been attended, from which it does not appear conclusive that an agent of insensibility is always employed by that physiologist during his experiments, although this may be done during the operation; but, on the contrary, that sometimes the animals have suffered pain. The medical journals and works published by physiologists have been examined minutely, and many pages of manuscript extracted therefrom. These conclusively prove: (1.) That vivisectional experiments on animals are frequently used by medical men and physiologists in this country. (2.) That in many instances no anæsthetic agent is employed throughout the experiments when much pain is necessarily caused. (3.) That the alleged object of such operations is scientific research and demonstration. (4.) That the same experiment is repeated many times on different animals. (5.) That an effort is being made to instruct students, by means of handbooks, in the practice of vivisections. Evidence has been taken from persons who have witnessed vivisections at medical schools, whose testimony shows that professors seldom operate on living animals before their classes, but frequently exhibit them alive after an operation has been performed, and always while the animal is insensible to pain; that the object of such experiments which are repeated *ad infinitum*, is solely to demonstrate facts previously established, and that students do sometimes perform experiments on living animals at their own chambers without the knowledge of their teachers.” [I have a paper with regard to this which I shall leave with you.] “Dr. Hoggan, whose letter on vivisections has caused much anxiety, has appeared before us on three occasions. He cannot give any particulars of practices which prevail in this country, his experience having been confined to laboratories on the Continent. He,

Mr. J. Colam.

19 Oct. 1875.

“nevertheless, states that Continental views on this subject and experiments are being rapidly introduced into England and Scotland, an instance being the employment of living animals to illustrate lectures in medical schools, which mode of teaching has long been the custom in Europe, but has only recently become general in the United Kingdom. The secretary of the deputation, Miss Cobbe, has been invited to supply evidence on which the allegations of the memorial were based, and more recently the medical signers of the memorial, about 70 in number, were addressed by letter, asking them to be good enough to supply data respecting those vivisections of which they had complained, or to point to sources from which we could obtain the same; but we regret to say that no new evidence has been obtained from the memorialists of a specific nature. We have also endeavoured to obtain information respecting the supply of animals to physiologists for the purpose of being used in vivisections. Much secrecy necessarily prevails on this matter, but we have discovered persons who are engaged in providing animals for the operations alluded to. These men are dealers in cats and dogs, and although naturally very reticent they have admitted taking animals to St. Bartholomew's and Guy's Hospital for experiments, and under regulations of a private and confidential character. Vivisection is a practice in which many conflicting elements are present, and where science, acting for the prevention of human diseases and human suffering, is brought into contact with suffering entailed on a vast multitude of animals, and it is therefore extremely difficult to arrive at a just determination as to measures which are necessary for the protection of animals. It becomes our duty, however, to endeavour to procure the adoption of some of stringent legal restrictions of the practice of vivisection. Avoiding any extreme measure, such as the total prohibition of experiments, a medium course should be taken with a view to prevent abuses and to confine experiments within as narrow limits as possible. Repetition of operations when deductions have already been established should be forbidden, and unskilful and unauthorised persons should not be permitted to perform experiments. It is still more essential that anæsthesia should be insisted on whenever experiments are performed, and continued during the experiment.” ‘The committee cannot doubt that vivisection has been considerably extended during the last few years; and though they cannot prove that students to any extent engage in it personally, they regret that lectures are illustrated to them by animals previously operated on, and that in such matter, as in others, Continental usages are being imported into this country. Such is the growing carelessness, that in one instance, perhaps unintentionally, a living lobster, they have reason to believe, has been cut up in the presence of a class of young ladies by their physiological teacher; while popular lectures are being given of a sensational character by a learned professor, who made his audience laugh over the grim behaviour of his unfortunate victims. The evidence which is now placed before you gives proofs only too abundant of the prevalence of painful experiments on animals, painless ones being left out of the extracts now submitted; that such pain is often protracted for days and weeks; and that a determined effort is being made to train students by the practice of experiments. Foreign experiments have been purposely omitted, except when these have been approved and recommended by English papers. (Signed) John Colam, Secretary.’*

1570. (*Chairman.*) That is the report of a committee appointed by the society to consider the allegations of the memorial?—Yes, with additions ordered by general committee for presentation to you.

1571. And it has been your instruction to make it known to us?—Yes.

1572. It may be taken then as the general opinion of the society that that is a document of great importance for us to consider?—Yes.

1573. You have said that a professor gave public lectures in which he sought to amuse his audience by a description of the grim behaviour of the victims of his experiments?—Yes.

1574. Who was that professor?—Professor Ferrier.

1575. Upon what evidence is the allegation founded?—Upon the evidence of newspapers, which reported his lectures, and upon my own personal presence at his lectures.

1576. We may take it that you personally have heard Professor Ferrier describe the infliction of severe suffering upon the animals upon which he operated?—I have heard him say that the animals “appeared” to be in intense suffering, and then joke about the stupidity of the animal, especially if the animal happened to be a monkey, giving humorous descriptions of its behaviour; so much so that at times there was general laughter in the lecture place. Three gentlemen were with me who are members of the committee of the society, and one of them left the room in disgust.

1577. (*Mr. Erichsen.*) Was that a popular lecture or a medical one?—A popular lecture. I think the place where it was given is called the London Institution, in Finsbury Circus.

1578. (*Chairman.*) Is that lecture published?—I really do not know.

1579. Were newspaper reporters admitted to it?—Yes, I presume so, as the public could enter, and the members of the institution were admitted. I think I have got a report of similar remarks which were made at a lecture in the north. I should say the whole of the lecture, so different from anything I had heard by experimental lecturers before, was interspersed with parentheses of laughter.

1580. (*Mr. Erichsen.*) The audience was not shocked then?—Not in the least.

1581. (*Mr. Huxley.*) Professor Ferrier's experiments were experiments on the different parts of the cerebral hemispheres, were they not?—They were.

1582. He was not operating before his audience, was he?—Not at all.

1583. But he was describing to his audience the effect of the irritation of certain parts of the cerebral hemispheres?—Yes.

1584. I take it, among those effects he described contortions of the face?—Yes.

1585. And contortions of the muscles of the limbs?—Yes.

1586. I presume that it may have been the case that those contortions were in themselves very grotesque?—Yes, one might have laughed if one did not know that the poor creature's head had been opened.

1587. As a matter of fact, when a monkey makes contortions of the face or moves its limbs about, it is actually very grotesque, is it not?—Yes.

1588. Then the laughter which it induced may have been from the inherent grotesqueness of the thing, and not from any desire of Dr. Ferrier to make it grotesque?—Yes; but the skill of the lecturer was used to cover the grim character of the experiment by his humour.

1589. The question here is a matter of interpretation as to what Dr. Ferrier meant. I presume it is perfectly impossible for a man to describe, even with the most serious intention, the curiously grotesque grimaces that a monkey would make under those circumstances without producing a laugh?—And without laughing himself, it would appear.

1590. (*Chairman.*) At any rate this statement is made by you not on your own authority, but it is laid before us from official documents, and by the desire of this society?—Yes.

1591. It was on some particular day, of course, that this lecture occurred?—Yes.

---

* Appendix IV.—Documentary evidence handed in by the witness.

Mr. J. Colam.

19 Oct. 1875.

1592. Can you tell us what day it was ?—I should think it is six months ago.

1593. But will you furnish the Commission with the exact date ?—Yes, if I have notes of it.

1594. And you can assist us in discovering whether any London newspaper contained any report of what actually took place ?—Yes. I could give you also a copy, I think, of a report of a similar lecture which he delivered in the north of England, when the same laughter happened. I would like to add that I should be very sorry myself to say that there was any design to make mockery of any suffering of the animals, because, so far as I could see, there was some evidence to lead one to believe that the animal was incapable of suffering at the time when the contortions he described took place; but what did strike me, and struck a good many other people, was that as there were several young people there, and several young ladies too, it was a long way out of good taste to be making use of such remarks.

1595. (*Mr. Forster.*) But am I to understand that these contortions that you are referring to were contortions of the animal under the influence of anæsthetics ?—Yes, I think it was after the removal of the brain when it was alleged that the animal would be incapable of suffering in some cases.

1596. (*Chairman.*) But what it is important for us to understand is this, whether this is brought before us as evidence of great and unfeeling cruelty on the part of the lecturer, or merely, as what you seem now to have put it, a departure from good taste ?—As a departure from good taste, and as sensational.

1597. Do I understand you on the part of the society to withdraw that altogether in the sense of being an allegation of great and deliberate cruelty ?—That was not meant for a moment. I attended those two lectures endeavouring during the whole time to discover evidence of suffering, and, with the exception of one small remark, which might be understood in two ways, it was impossible to discover whether there was any suffering on the part of the animals at all in the descriptions given.

1598. I consider this an important document put before us by the society, and I should like very much that we should thoroughly understand what we are to consider them as putting before us. Are we to consider that it is to be examined by us as an allegation made against this particular professor of doing that which I understand you to say professors generally do not do, namely, exhibiting great habitual indifference to the sufferings of animals ?—No; but merely as a case of levity, likely to produce a bad effect.

1599. (*Mr. Forster.*) What do you mean; levity at the contortions of the animal, or levity at the contortions of the animal caused by pain ?—Simply levity on the subject generally; the lecture was made what is called popular.

1600. (*Chairman.*) But the important thing you will observe is, that we should know whether it is an allegation against a particular professor of great indifference to the suffering of the animals ?—I think not.

1601. Then for what particular purpose is it made so important a feature in a document of the Society for the Prevention of Cruelty to Animals ?—Because it struck the members of the committee, as it did myself, that there was scarcely that decorum which you would expect, and that one ought really to see, in a man who was describing the condition of animals which had been mutilated by himself. There was not a word of commiseration or regret that the experiments were necessary, but there was amusement offered for the audience.

1602. But I understand you now to express belief that the animals had not suffered, but that they had been under chloroform the whole time ?—He did not say; we could not gather at all whether they had been under chloroform; but I am inclined to think, from the nature of the experiments, it was absolutely necessary that they should be.

1603. Do you mean us, as far as you can guide us, to understand that these animals had been subjected to great suffering, or that, whatever had been done to them had been done under complete anæsthesia ?—I would rather be inclined to think that the animals did not suffer, judging from the description given of the experiments, and from what I have read myself in the various books which I have been obliged to read. The allusion to the experiments of Dr. Ferrier in the paper which I have read, where there is an intimation that sometimes there is suffering, is to cases where he states that the animals have remained under the operation for several days.

1604. (*Mr. Forster.*) I understood you to say that you thought the reason why there was no suffering was because the brain had been removed ?—Yes, after the operation had been completed the effect of the narcotic would cease in most cases before the experiment had been concluded.

1605. Do you think that it was that there was no suffering because chloroform, or some anæsthetic, had been administered, or because the brain had been removed ?—Of course we did not see the experiment, we only heard a description of it, and I should think that chloroform must have been used during the operation. I am inclined to think it would kill the animal to perform the operation without chloroform, the effect of which would last until perhaps after the brain has been removed partly or wholly; therefore in the first part of the experiment there would be no feeling owing to the presence of a narcotic, and in the second part of the experiment owing to the removal of the brain.

1606. (*Mr. Hutton.*) May I ask you to explain your statement that the lecturer joked about the stupidity of the monkey. Those movements were involuntary, were they not ?—Of course they would be, because he showed that the animal had no volition at all.

1607. And therefore it was meant as a sort of joke upon the apparent expressions of the monkey ?—Yes, and the loss of intelligence of the animal also.

1608. (*Chairman.*) Have you any record at the society, any newspapers filed, that contain a record of this lecture ?—I do not think that a report of the lecture appeared in any London newspaper. Probably newspaper reporters do not attend at the London Institution on such occasions; and therefore there would be no report of it. Two barristers were with me, one Mr. Robert Sawyer, and the other Mr. Thomas Allen, and another member of the committee, Mr. Thomson; and one of those three gentlemen left the room in consequence of the pain with which he saw the laughter of the young people.

1609. (*Mr. Forster.*) I thought you stated that there were reporters there ?—I did not see any reporters there.

1610. But you stated something about reports of the lectures appearing in the newspapers ?—That was in the north of England.

1611. (*Mr. Erichsen.*) Did not this lecture consist of a description of the movements induced in an animal by stimulating certain portions of the surface of the brain by electricity ?—Yes, in some cases.

1612. And consequently the brain could not have been removed ?—I cannot pretend to be very accurate in these matters, except with regard to the impression produced on one's mind by what we heard. I think the skull was only opened in some cases, and in others the brain was also partly removed; but I would rather not answer any questions in detail about that, as the experiments were not made before us, but only described.

1613. The contortions of the animal in that case were simply the natural movements of the animal brought into operation by the stimulation of certain portions of the brain ?—Undoubtedly, in some cases.

1614. (*Mr. Forster.*) You mentioned another case, that of a living lobster being cut up before a ladies' school; could you give us any more particulars about that case ?—It was a lady who was the teacher, who had commenced a course of physiological lectures at

Mr. J. Colam.

19 Oct. 1875.

a school which is about 20 miles from London. The complaint was sent to us in the ordinary way under a pledge of secrecy; that is to say, of course the complainant did not wish to be known. It had been told by one child to its parent, and the parent communicated it to us, and we caused inquiry to be made. I sent down one of my assistants. (I did not send an officer down; under the circumstances I decided not to do so), and he saw the lady to whom the school belongs, and he learned that the facts were—that the teacher did take a lobster and put it upon the table, and then cut it; and after one portion of the lobster had been severed there was something more than muscular action, for a part of the lobster crawled upon the table.

1615. Was any chloroform or other anæsthetic administered?—No. The explanation given by the lady is, I believe, that she bought the lobster on her way there, and did not know that it was alive; and I think that is likely to be the case, only I think she was a bad physiologist.

1616. (*Mr. Huxley.*) The shortest and best way to kill a lobster is to cut into its pericardium, and she may have done that as the best way of killing the thing without any bad intention whatever, may she not?—I am told that she concluded that it was dead.

1617. (*Mr. Forster.*) But I think in the mention of this case in the report you make no allusion to that explanation?—It is said that it was carelessness; there was no desire to misrepresent the matter, and we were really under a pledge of secrecy not to divulge the name. These are the words of the report: "Such is the growing carelessness that in one " instance, perhaps unintentionally, a living lobster " they have reason to believe has been cut up in the " presence of a class of young ladies by their physio- " logical teacher." The description given to us by the lady of the school showed that it was true.

1618. (*Sir John Karslake.*) Had she heard it from the little girl?—She was present when it was done, and was horrified by it.

1619. (*Mr. Forster.*) With regard to this lady lecturer, I do not wish to ask her name, but was she a teacher in the school?—No; a physiological teacher.

1620. (*Mr. Erichsen.*) Was she a medical practitioner may I ask?—I think not.

1621. (*Chairman.*) Is it possible to imagine that a lady could buy a lobster, carry it in a cab, put it on a table, and keep it on the table, and then proceed to cut it up, and then for it to crawl about afterwards, and that she did not know during the interval whether it was alive or not?—The lady had in her bag at the same time a dead rabbit on which she experimented before the class, and she is in the habit now of doing the same thing; and I believe that it is her explanation, that she thought the lobster was dead; and I think it is consistent. I think Professor Huxley will agree that so far as we are concerned we are not guilty of any misrepresentation; we have simply used the words put into our mouth, that it was cut up,—in what way we cannot say,—except that there was one portion severed from the body, which did move, and which horrified the people there. To tell the truth, the lady of the school was extremely anxious that no further inquiry should take place lest it should do damage to the school.

1622. (*Sir John Karslake.*) There was a portion of the report of your society in which reference is made to the growing practice among students in some parts of the country of carrying on vivisection; will you just read that portion again?—I think there is an allusion to the circumstance that evidence had been obtained in one case of experiments by students at Edinburgh (as is shown in the paper which I hold in my hand), which experiments were performed by them in their private rooms; but it is qualified here by saying "unknown to their teachers."

1623. Will you read the paragraph of the report in which that is referred to?—I will read from the report an allusion to students being taught vivisections, which is as follows:—"A determined effort is " being made to train students in physiology by the " practice of experiments."

1624. On what foundation does that statement rest?—On several facts. In the first place, a handbook has been published which is designed for no other purpose than to teach beginners, the preface of which declares that it is for beginners, which gives 63 experiments involving pain, and gives a full and detailed account of every instrument that is required for experimentation in order that it may be as plain as possible to the mind of a beginner. This book says the experiments may be repeated any number of times.

1625. What is the name of that book?—The Physiological Handbook, edited by Dr. Burdon Sanderson, in which papers appear by Dr. Klein, Dr. Burdon Sanderson, and Dr. Michael Foster.

1626. Is it upon the fact of that handbook having been published that that paragraph finds its way into the report?—That is part of the reason.

1627. What is the other part?—The other part is that at various meetings which have been held, teachers of physiology have insisted not only upon the desirability but upon the duty of bringing students into laboratories, and instructing them in laboratories by experiments upon animals performed in the presence of the students. Dr. Rutherford is an instance.

1628. What other gentleman can you mention as an advocate for that practice?—Dr. Brunton also told me that if the students were not taught to manipulate and to experiment the next generation would be found without any experimenters, and therefore it was desirable that they should be taught. So far as he was concerned he thought it was right that they should be taught the experiments.

1629. Did that apply, as you understood it, to all students, or to a certain class of students?—To all students who wished to become physiologists; but all medical students are required now to study "practical physiology."

1630. And did he limit at all the cases in which he proposed that these experiments should be made before them?—No.

1631. He did not define them at all to you?—No.

1632. Now, in your own personal experience, which you say has existed for about 15 years, have you known instances yourself where cruelty has been practised by private medical men in their own houses towards animals?—Not any.

1633. Or, as far as you know, has that come to the knowledge of the officers of the society?—As far as I know, it has not.

1634. I ask that question because, as I understand the Bill which the society has laid upon the table here, it is proposed in that Bill that, in the event of reasonable suspicion attaching to a particular person, a justice of the peace might issue a search warrant?—When it becomes necessary to obtain a license, and when persons have to go through a form to get that license, there might probably be a temptation to some persons to perform experiments without really having been properly qualified. This will account for that provision.

1635. With regard to that proposal in the Bill which you have laid before us, is there any instance that you know of in the course of your experience during the last 15 years, or any instance reported to you by your officers in which you would have put that section into force?—Yes; cases have often been reported to me as rumoured.

1636. Was it a mere rumour or was it founded upon any evidence at all in those cases?—Not evidence exactly—strong suspicion perhaps, but not conclusive evidence; but observe, your question was with regard to medical men. Of course medical practitioners as a rule do not perform many experiments.

1637. Now, I understood you to say that there were a class of men who were known to your society who supply animals to the different laboratories or schools?—Yes.

1638. From whom did you get that information?—We got information by watching.

1639. Now, may I ask you this. I think you said that there were certain regulations under which those men supplied the animals to those who employed them?—Yes.

1640. From whom did you hear that there were certain regulations?—From the men themselves; the officers of the society report that to me.

1641. Can you tell us any hospital to which it is alleged animals are supplied, and where particular regulations are issued to the suppliers of those animals as to the mode in which they are to be supplied to the hospital?—Yes, certainly; St. Bartholomew's.

1642. Who would be the person who would probably have to give those instructions if they exist?—The porter at the gate.

1643. And I suppose he would act under the physiologist or some person there who has the conduct of the experiments?—Yes; Dr. Legge or Dr. Brunton, I should think.

1644. (*Mr. Huxley.*) With regard to the case of the lobster which you mentioned, I suppose you know what commonly happens to lobsters?—With regard to boiling them, I suppose you mean, yes.

1645. Does the society ever interfere on that point?—I have been down myself to see them at Billingsgate put into the water, and they die instantly.

1646. But they are put into boiling water?—Yes; I have been there several times in the middle of the night for the purpose of seeing it done, and have found no cruelty.

1647. I should like to ask you a few questions as representative of the society, as to what you conceive would be the effect of the Bill now before us, supposing it to become law. There is a famous experiment which was made a number of years ago on which a great deal of our present knowledge of the physiology of the nervous system is based, called Bell's experiments on the roots of the nerves. It cannot be performed without the infliction of pain. Would the Bill, if it became law, stop an experiment of that character?—I scarcely know the nature of the experiment, not being an expert.

1648. I take it for granted that the experiment is a very painful one, and cannot be otherwise. The Bill would stop it, would it not?—Yes; but you must remember that Sir Charles Bell said about that particular experiment that he merely performed it for the purpose of convincing people who did not use inductive reasoning, and Dr. Ebenezer Watson, himself a vivisectionist, the other day publicly stated that it was the greatest satisfaction to his mind to know that that great discovery was established by only one experiment on one animal, and that experiment was for demonstration.

1649. Suppose that an experiment having a similar value in relation to physiology needed to be performed would the Bill, if it became law, prevent its being performed?—As in our Acts of Parliament magistrates have to construe what cruelty is, and as now there are some things which might certainly be considered cruelty which no magistrate in the world would convict for, so magistrates might be left to construe what pain is under the new statute.

1650. Does this Bill of yours leave any discretion to magistrates?—I must admit there is no room left for much discretion. Such animal, it says, is to be submitted to the influence of an anæsthetic, so as to render it wholly insensible to pain.

1651. The Bill says that the animal is to be wholly insensible during the time that the experiment is being performed, does it not?—Yes.

1652. In that case a magistrate would have no discretion whatever, would he?—A magistrate would have the discretion certainly of dismissing the case if he chose.

1653. That is to say, if he thought it could not be proved that there was pain?—Yes.

1654. But I am now supposing that to be admitted. I am supposing the case to come before the magistrate in this way, that it is admitted that as much pain was given as would be given in that particular case I have mentioned, would your Bill prohibit it?—I admit it would. I do not wish to be uncandid.

1655. I understood you to mention with reprobation the experiments made by the Medical and Chirurgical Society on dogs in order to ascertain whether the methods of restoring life in cases of suspended animation could be improved. Therefore, I presume that this Bill, if it becomes law, would stop all such experiments as those?—I hope so.

1656. Can you tell me whether the Bill, if it became law, would have the effect of stopping such experiments as those which have been recently made by Dr. Klein, and which have thrown such very great light on the nature of small-pox; that is to say, sheep have been inoculated with sheep-pox, and the whole course of the disease has been studied in sheep. No doubt that gave the sheep a certain amount of pain; now would the effect of the Bill be to stop all experiments of that kind?—I really am not competent to say whether the experiment would in that case be considered pain, or whether it could be performed with an anæsthetic.

1657. Undoubtedly sheep-pox is a painful disease. I am supposing that to be admitted?—That is hyphothesis, I think.

1658. There is as much reason to suppose that a sheep is uneasy when it has sheep-pox as that a man is uneasy when he has small-pox, and we know perfectly well that a man is uneasy when he has small-pox. Now, supposing that Dr. Klein, or any such person, were engaged in experimenting in that way, under your Bill, if it became law, it would be possible for a person to lay an information against him, and he might be dragged before a magistrate and charged with committing a breach of the law. I wish to ask whether that would be a breach of the law in your judgment?—As the representative of the society I must say yes, if painful.

1659. About a hundred years ago there was a French Abbé, named Trembley, who made a number of experiments upon what is called the hydra, a fresh water polyp; he made transverse sections and longitudinal sections, and he discovered, what was a very wonderful fact, and one which effected a great revolution in the way of thinking in those days, that each of these things would grow up into a new polyp. Suppose a person were to repeat those experiments in the present day, or anything like them, in your judgment, would he come under the operation of this Bill if it became law?—I must answer in the same way, that assuming that there is pain he would; but I am not inclined to say there was pain inflicted in that case.

1660. There is no limitation in your Bill as to the kind of animal or as to how much pain is inflicted?—No.

1661. One of the commonest things shown in a class is the circulation of the blood in a frog's foot. To show that you have to tie the frog's toes out, and otherwise make him more or less uncomfortable, and then you see the circulation, which is a very wonderful sight. Should I, as a teacher of physiology be prohibited from performing that experiment if this Bill became law?—I should think not. I should think that would scarcely be called pain.

1662. I beg your pardon. I should admit at once that there was pain there?—Speaking microscopically it would be pain, I suppose.

1663. I want to know what physiological people are to expect if the Bill becomes law?—At the present time you must remember there is an Act of Parliament which provides that you shall not illtreat or torture an animal; and in applying the law therefore at the present time, it has to be determined what is torturing or ill-treating an animal. It might be contended in a given case that there had been ill-treatment or torture in a very small degree, and thus if Dr. Klein's sheep were tortured no more even than your frog in the case you have put you might possibly contend that now under the present Act we could take Dr. Klein

Mr. J. Colam.

19 Oct. 1875.

before a magistrate; but you must remember that no society, no prosecutor, can ever go beyond public opinion, and therefore it is idle to talk about infinitesimal cases of that kind, I submit.

1664. I think you said that you thought it would be desirable that the Bill should give the society power to test whether experiments were doing any good?—I said that the object would be twofold; the first advantage would be that it would enable the society and every person else to judge, from the register of experiments performed and the results which had been achieved, whether the experiments were of any value at all. Secondly, it would prevent a repetition of experiments, because the publication of the experiments would go to the ends of the earth, and prevent any unnecessary repetition of experimentation.

1665. Then am I to gather that you think that the Society for the Prevention of Cruelty to Animals is a fit high court to which to refer scientific inquiry, to judge whether a particular class of experiments is doing any good or not?—I beg your pardon, I did not mean anything of the kind.

1666. I ask the question because that is one construction which your words would bear?—I did not mean that; I meant this, that all persons would be enabled to form a judgment, and I suppose members of the Royal Society for the Prevention of Cruelty to Animals can form a judgment as well as those who are not members of that society, some of whom are very well able to form a judgment scientifically. It would enable them as well as other members of society at large to form a judgment on that question.

1667. But in the long run it would constitute the society judges of the scientific value of a given result?—Only as we are judges now of anything; judges, for instance, of the operation of any Bill that may be brought in during the next session of Parliament.

1668. (*Mr. Forster.*) You mean that it would give that publicity which would enable you to form an opinion of the value of the experiments?—Yes.

1669. (*Mr. Huxley.*) But I do not see how any but experts can form any opinion as to their value. I want to know whether that is one object of the Bill to constitute the Society for the Prevention of Cruelty to Animals a sort of court of revision in these matters?—Do you not think, I may ask, the society would be able to judge whether for instance the experiments referred to by you had prevented sheep disease or cattle diseases or not, if those diseases disappeared by the application of the remedies discovered by the experimenters.

1670. No, I think not. I think that if the society contented themselves with reading Dr. Klein's memoir recently published, unless I am much mistaken, there is not one in 500 who would understand anything about it?—Not the technicalities; but the general results we might understand. I hope so, else I think the experiments would be of no great advantage to humanity.

1671. (*Chairman.*) What I understand you to say is that you wish this Bill of yours to be understood as subject to reasonable interpretation like all other Bills for the prevention of cruelty?—Of course.

1672. And if the terms of it are such as to exclude a reasonable man in the chair of the magistrate from determining whether there is cruelty in the particular case, you do not think the society would insist upon those particular words?—I think not.

1673. Then the only purpose for which the society are to be judges is whether it is a case in which they ought to institute a prosecution?—That is so.

1674. And then it would be for the court to determine whether they had sustained that prosecution?—Yes.

1675. And experts might be brought forward for the defence if it was desirable that the evidence of experts should be heard. Is that what you wish us to understand?—Yes, as in the case of the Norwich prosecution, which I conducted myself. We had there doctors against us and doctors for us, and the contention was then, as would be under our Bill, was pain given or not.

1676. The phraseology of the Bill, as you have laid it before us, does not seem to some of us to admit of that reasonable interpretation, but seems to be too precise, that the court must necessarily act upon the mere words without taking the reasonableness of the thing into consideration at all. If such should be the true legal interpretation of this Bill, are you authorised on the part of the society to say that they would wish the words to be qualified?—The society consists of practical men and reasonable men. In discussing this Bill before the Government I am obliged to state that it would be impossible for the society to move from their position.

1677. But you have now been asked whether, if your Bill were to pass through Parliament in the shape in which you have submitted it, such and such consequences would not follow; and you have said that in all other cases, and particularly you say in the Norwich case, the reasonableness of the conclusion is submitted to the judgment of the court; would you take upon yourself to say that the society really wish that in any Bill which should be framed in obedience to their suggestions, the reasonableness in this case also should be taken into consideration?—Yes; of course they would be very glad to have the most reasonable phraseology used.

1678. (*Mr. Forster.*) I want to ask you a question following upon Professor Huxley's questions, not so much as regards the actual wording of the Bill, but as to the intention of the committee of the society with regard to legislation so far as you can give it. Now it has been stated to us in evidence by Mr. Simon that he considers that by giving animals a disease, and I imagine a painful disease, he obtained information with regard to cholera which he considers is of very great service in sanitary legislation, and in enabling an Act of Parliament to be passed which will very likely diminish cholera. Now if this Bill had been passed, or if any Bill had been passed such as your society wishes before he tried such experiments, would they or would they not have desired that he should have been prevented by law from trying them?—I think if it were any very severe infliction of pain on animals, perhaps the society would like to have prevented that. But the society has come to the conclusion, from reading the history of vivisection, the history of the experimentations, that one generation of experimenters arise for the purpose of correcting the other experimenters, and that each generation of experimenters has really some panacea which turns out afterwards to be of no value at all.

1679. My question was not with regard to vivisection, but with regard to the giving of disease. What I wanted to know was the exact desire of the society. Do you think that the object of that committee of the society which has framed this Bill would be to prevent such an experiment as that, and that in fact the law which they would wish passed would have prevented that if it had been passed?—I think so if it were a very severe act of cruelty.

1680. I have interpreted it to be the giving of a disease?—A disease might be given, I apprehend, without much pain being caused to the animal.

1681. But before you would have allowed that thing to have been done you would have required not merely to have been satisfied that there was a reasonable probability that it might result in the prevention of cholera, or do something towards the prevention of cholera, but you would also have wished it to be proved that there would not be severe suffering caused to the animal upon whom the experiment was tried?—I am quite sure that the society would not prosecute, although they might desire the law, in any case such as you are suggesting, and I say that from the course which is taken now very frequently, for instance, in a case where a horse had been over-ridden to save a life.

1682. (*Mr. Hutton.*) Have you handed in the evidence of the cases of experiments by students in Edin-

Mr. J. Colam.

19 Oct. 1875.

burgh, to which you have referred in your written statement?—Yes, I have.

1683. You have nothing to add to what is written there?—No; except that in regard to London I have not been able to find a single case where the students have been employed.

1684. Are the names of the students given and the nature of the experiments in the paper which you have handed in?—Yes, of my informant.

1685. (*Chairman.*) Will you read the paper you have with regard to experiments made by students?—Yes. This is a statement made by a student of Edinburgh, and since Lecturer at the New Veterinary College, Edinburgh, on Materia Medica, who saw Mr. Ernest Hart's letter in the newspaper and wrote to us in consequence.

1686. And by the desire of the society it is laid before us?—Yes.

1687. (*Mr. Huxley.*) What is the date of it?—I think it is about six months ago. "Observing from the daily papers that Mr. Ernest Hart alleges that students do not perform experiments on living animals as an exercise in the prosecution of their studies, I beg to forward to you a summary of my experience in that respect during my college career at Edinburgh. I am a veterinary surgeon, and comparatively unknown, but I feel it my duty to aid your society in repressing unnecessary experimentation, surveying the past as I do with much regret, so far as I have participated in the practices which I am now compelled to condemn. At Edinburgh the veterinary students and the medical students frequently associate for pleasure and for study. During my first term I was admitted only to two private meetings where experiments were conducted by students alone; but in the following term, having become a senior, I was introduced to a great number of such vivisections, and on some occasions operated myself. The experiments were certainly never designed to discover any new fact to elucidate any obscure phenomena, but simply to demonstrate the most ordinary facts of physiology. Our victims were sometimes dogs, but more frequently cats. Many of the latter were caught by means of a poisoned bait, the animal being secured whilst suffering from the agonies caused by the poison, when antidotes were applied for their restoration. They were then imprisoned in a cupboard at the students' lodgings, and kept there until a meeting could be arranged. Sometimes the students secured their victims by what is known as a cat hunt, that is a raid on cats by students armed with sticks late at night. I am not prepared to say that the object of the students was to commit cruelty, or that there was any morbid desire to witness pain, but I say emphatically that there was no other motive than idle curiosity and heedless reckless love of experimenation. What, for instance, could justify the following experiment, performed for the purpose of witnessing the action of a cat's heart? The operator first of all made an incision through the skin of the animal's chest extending from the neck to the belly. The skin was then laid back by hooks, in order to enable the operator to cut through the cartilage of the breast-bone, and to draw his knife across the ribs for the purpose of nicking them. This process is necessary to enable him to snap the ribs and lay the fractured parts back, which also are secured with hooks. It is needless to say that such operation is a most cruel one; but it is only one of several others performed at Edinburgh. Now, the action of the heart is well known, and is one of the first things taught to students of physiology, and can be taught as well without experimentation as with. In a few cases the animals were narcotised, when no suffering was caused either in the process of poisoning or in the after experimentations. The securing an animal for an operation like the above requires experience and care, and it is fearful to witness the struggles of the animal while this is being done. I desire to exonerate the professors from any participation in the experiments performed by students which were conducted at the private lodgings of students, when none but students were present. I merely write this in order to give my humble corroboration of the statement made in the memorial, that students are in the habit of performing experiments. James B. Mills, M.R.C.V.S." The writer of that letter is a veterinary surgeon at the present time in the Royal Artillery at Woolwich.

1688. He does not state whether that particular experiment which he describes with so much detail was made under the influence of narcotics or not?—No, he does not, except by saying that it was a most cruel experiment.

1689. (*Mr. Erichsen.*) I should like to put a question in reference to what came out in the evidence of a very eminent surgeon at the commencement of this inquiry, with regard to the provision in the proposed Act by which it becomes incumbent to administer anæsthesia in all painful experiments. An inquiry was mentioned to us, as of the very utmost possible practical character, which is necessarily attended with considerable pain, and that is in the discovery of an antidote to the snake poison; there are at least 10,000 people who die every year, in India from snake bite; and there is no possibility of arriving at any knowledge of an antidote for snake bite, and consequently no hope of saving the lives of those people except by submitting animals to be bitten by snakes and then testing the power of the alleged antidote upon those animals. That, I imagine, would be a very painful experiment to the animal, and it would be impossible to perform that experiment under anæsthesia, and yet the result of such an inquiry might have been of inestimable service to humanity and a direct service because it is not a scientific, but a purely practical inquiry. Would the provisions of the Bill interfere with such an inquiry or investigation?—I presume they would, but at the same time I would say that Sir William Fergusson, another eminent surgeon, has expressed a very strong opinion that these experimentations are entirely useless.

1690. No result has as yet been arrived at, no antidote has yet been found, but the only hope of discovering an antidote, as Sir James Paget told us, in the next 20 years, would be by continuing experiments of that kind on animals. Is it your opinion that the Bill as proposed would interfere with the performance of such experiments, which would be of the most direct practical benefit to mankind, and would, if successful, save the lives of thousands annually?—It would be of value to mankind if it would save lives; but that is the whole question I presume. If it could be established at once that an experiment would yield a blessing to mankind the result would be already known, and there need be no experimentation at all; it is the uncertainty of the thing that requires experimentation. I therefore would not admit the premiss that the experiment would necessarily be of the most direct practical benefit to mankind.

1691. (*Chairman.*) But the question put to you is whether your Bill would prevent the process which the Government of India are now carrying on for the purpose of preventing the loss of life by snake bite?—I am afraid it would.

1692. Take another case; we have been told that the condemnation of Palmer for one of those numerous murders, and the condemnation of other criminals, has been very much due to certain experiments made upon animals by the use of strichnine or other poisons; would your Bill prevent that?—I am afraid it would. But at the same time, I would like to say that it is a very difficult thing to answer these questions in the way I am doing now, because I have in my mind at the same time the statements made by a man like Sir Charles Bell, who says that experimentation has not yielded the results claimed for it. I am not going to say that experimentation has not yielded anything; at the same time, I cannot allow it to be assumed that the experiment is going to answer.

Mr. J. Colam.

19 Oct. 1875.

1693. But we are assuming nothing, except that it is the object of the experiment to discover a cure for snake bites, or to bring a murderer to justice. Would your Bill prevent an experiment as to the effect of strychnine on an animal, or subjecting an animal to a snake bite?—I should say so; but I am sure Sir John Karslake will tell you that there are many things which you must not do, even to bring a murderer to justice. Although it would be a good thing to bring a murderer to justice by certain short cuts, the practice of the courts do not admit of them, because the end does not justify the means.

1694. I want you to understand that the object of the questions which have recently been put to you, and are now being put to you, is not to argue it one way or the other, but merely to ascertain whether the effect of this Bill, if passed in the sense in which it is submitted to us by the society, would be to render such experiments impossible?—I think so.

1695. However strong the scientific opinion in favour of the experiment might be, do you think that those who have submitted that Bill to us would wish the Bill to pass in a form which should render the experiment impossible?—I think that they would like to have it passed in this form, and if that is not possible, then to get it as near as possible to this form.

1696. (*Mr. Forster.*) Do you think that they have had before them at all this case of snake poisons?—Yes, I think those cases have been before the committee.

1697. Could you tell us whether it occurred to them that there was any other way of finding out whether a supposed antidote was likely to be an antidote than by giving an animal poison, and then the antidote, to see whether it cured it or not?—There are many ways, perhaps. I have seen experiments to test the action of poisons upon dead animals, upon the hearts of frogs, for instance. The heart has been taken out from the body of the animal, when the pulsation continues for a long time; and I have seen the poison tested in that way without any cruelty at all. I do not know that that would be applicable in all cases, but there may be some other means by which the want would be met. It may be a more easy and a more rapid way of doing the thing, and one that would prevent a good deal of thought and study to experiment on a living animal, but the question is, is it right. I do not say absolutely that it could be arrived at in any other way, but I say it is possible it might be; but it would be better to kill the snakes than to allow them to go on biting people, and then provide antidotes by killing and torturing other animals.

1698. (*Mr. Huxley.*) Did I rightly understand you to say that the society, in drawing up this Bill, have been actuated, among other things, by a firm belief that physiological experimentation has not done much towards the discovery of new truth?—I think that is the general impression of the society, as regards the treatment of disease.

1699. On whose authority may I ask?—When I speak of the society I am speaking of the committee rather, the society itself consists of many members.

1700. Is there anyone in the committee who is conversant with the history of physiological science in the last 20 years?—Yes, I think so. There is one member of the committee who is a doctor of medicine, and has had a good practice at the West End, who says he does not believe vivisection has done any good to his profession; and another member has made the subject a special study, is the author of several medical books, and the editor of a journal which includes physiology and anatomy, entitled *The Veterinary Journal.*

1701. (*Chairman.*) In giving in the documents connected with the committee, have you given the names of the committee?—No, I have not.

1702. Will you do so?—Yes.

The witness withdrew.

Adjourned to to-morrow at 2 o'clock.

Wednesday, 20th October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq. Secretary.

Mr. A. de Noé Walker.

20 Oct. 1875.

MR. ARTHUR DE NOÉ WALKER called in and examined.

1703. (*Chairman.*) I think you were originally a military surgeon, were you not?—Yes.

1704. You then became a private practitioner in London?—Yes.

1705. And on the occurrence of the Crimean War you desired to return *sub modo* to the military service, and were attached to a regiment in the Crimea?—Yes.

1706. And you have since that returned to practice in London, and are now a physician?—Yes, I have been in practice ever since in London.

1707. Now I believe you have had considerable knowledge on the subject into which we are inquiring, and have been a student in physiological laboratories chiefly on the Continent?—Yes, in two or three, and I have read up generally what has been since published.

1708. And you have kept yourself acquainted, through foreign publications and English publications, with what is going on generally upon the subject?—Yes.

1709. You have paid special attention to it probably since it became rather more generally interesting to the public than it was before?—I particularly looked into the working of physiological laboratories from 1856 to 1857–58, and again in 1872.

1710. When you were studying in physiological laboratories abroad what was your general impression with regard to the sufferings of animals?—My general and very decided impression was that a great deal of it was wanton and unnecessary.

1711. Do you believe that there is anything of the kind which you there condemned in this country now?—Not from my own personal experience in physiological laboratories in this country, but from reading experiments published in this country, there is, I believe, much to be condemned.

1712. Are you disposed to say that what you saw uncondemned in foreign laboratories still continues?—I have every reason to believe so.

1713. Can you support that opinion by a reference to any publications, foreign and English?—Yes, certainly.

1714. You understand that I particularly put that question to you with reference to what is going on abroad at the present moment?—I read every week

Mr. A. de Noé Walker.

20 Oct. 1875.

the *Gazette Médicale de Paris* which contains more about experiments on living animals than any weekly publication that I am acquainted with.

1715. Now could you give us from that publication, or from any other Continental publication, extracts which would illustrate the opinion that you have expressed?—Yes.

1716. Will you have the kindness to do so?—Yes.

1717. Have you observed in the last two or three years any tendency to the extension of these practices in this country?—As far as I can judge, from reading what is published, I should say they were very much extending indeed. It is almost a new phase of research, and is extending everywhere.

1718. Do you consider that there is a necessity for interference on the part of the State, to prevent the occurrence in this country of what you have seen obtain in other countries?—Decidedly; and I think it can be done without the least interference with scientific research, but rather the contrary.

1719. Are you prepared to support that view by extracts from publications in this country?—Yes, to a less degree than I could abroad, but I can bring forth enough to support my assertion.

1720. I think you have been suggested to us as a witness of medical authority who will represent to us the evils which are already resulting, or are likely to result, from the extended practice of vivisection, as it is called, in this country; you are in communication, I think, with the Society for the Prevention of Cruelty to Animals, they have asked you to come and give evidence?—Yes. But I perceived the necessity of limiting and legally controlling the practice many years ago, and commenced agitating the question long before I had any communication with the said society. I had compiled my notes, in the hope of appearing before this Commission, long before the society communicated with me.

1721. Will you specify the points, as they occur to you, in which you considered those consequences likely to follow?—The knowledge of vivisections, or rather experiments, that I have, consists, first, of vivisections performed solely with the object of studying physiology, of acquiring that is, knowledge of the healthy functions of animal life; secondly, of vivisections occasionally made with the object of ascertaining if certain surgicial operations are likely to prove successful in the human subject; thirdly, of vivisections made with the object of acquiring manual skill, with the view of performing the same operation on the human subject; fourthly, of experiments made with the object of studying the effects of traumatic lesions; of experiments made with the object of studying the effects, pathogenetic or toxic, of certain gases, mineral and vegetable substances, of certain animal fluids, and of the electric current. The greatest number of vivisections are made of course under the first head (to my knowledge at least), that is to say, for the purpose of acquiring knowledge of the healty functions of the human body; and it is here that I think the greatest amount of evil to be done away with exists. I need not, I suppose, enter into the question of how many physiologists, I mean attached to schools of medicine, are constantly misleading their pupils as to the purport of these experiments. Practically, as I was told by the last vivisector under whom I studied, this knowledge "has no other object in view than that of "contributing to the progress of medicine, and medi-"cine has no other object in view than that of healing "disease, the restoration of health to the sick being "evidently the ultimate end of all the physician's en-"deavours." If therefore physiological knowledge is or has been, therapeutically, of any use to the physician, it must have been the means of directing his mind to the discovery, or at least selection, of certain remedial agents. This is in fact that which experimental physiologists have been promising the medical profession for some centuries, and particularly since Réaumur commenced his experiments on the digestive functions 122 years ago. If now we place before us all the oldest and most recent works on practical medicine, as well as the best clinical records ever published, and patiently search through them all, in the hope of finding a single instance in which this promise has been fulfilled, we shall fail. I will explain what I mean by that, because it is very strongly stated. I mean to say that the knowledge of the healthy functions of animal life does not contain in itself any knowledge that can lead us to therapeutic agents for the treatment of any disease by which those parts may be affected. If one therapeutic agent has been occasionally suggested, has anyone ever found it of any use? I will not seek to prove this by referring to any of the complex and often mysterious functions or diseases of the nervous system, but will refer to the physiology of the heart, and to the discovery of the circulation of the blood, as not only highly interesting, but very well known, and the constant boast of vivisectors. Did physiologists, ancient or modern, after mastering the mechanism and innervation of the heart and general circulation, announce that digitalis, aconite, spigelia, belladonna, iodide of potassium, &c., &c., would affect the heart and circulation in any one way whatever? Secondly, now that physicians have informed physiologists of most of the effects and symptoms those agents produce on the heart, can they tell us why and how they so act? Thirdly, even if they could now explain the elective action of those particular substances on the healthy or diseased heart, how could that knowledge enable them to state what other agents could act in an analogous way on the same organs? Ignorance, however, of how or wherefore a remedial or other agent acts in a particular organ or tissue would, I think, be condoned if any vivisector, from his knowledge of the healthy functions of any one organ or tissue, had in a single instance deduced that a certain agent would act in that particular organ or tissue, either in health, or when attacked by even one, of the many diseases to which it is liable. Again, I say, how was it that after mastering the physiology of the iris, the physiologists did not turn round to the physician and surgeon and inform them that belladonna would dilate, and that the Calabar bean would contract it? Was it through a knowledge of the healthy functions of the human body that the discovery was made that lemon juice could cure and prevent scurvy, that opium will lull pain, mercury and iodide of potassium neutralize syphilitic virus; that colchicum will often cure gout, and quinine intermittent fever? If as some, indeed most physiologists, believe, that the disease called diabetes originates in the liver, and therapeutics are to be studied and practised according to our knowledge of the healthy functions, why is not some course of treatment suggested for that disease? I beg to observe to the Commission that I am not now dealing with the question as to whether physiological knowledge is or is not useful to the physician; neither is it my wish to appear to undervalue physiological knowledge. I am confining myself under this first head to vivisections made with the sole object of acquiring physiological knowledge, and my proposition is that that knowledge, acquired at the cost of intense suffering to millions of victims, has never been the means whereby any one remedial agent has been discovered for the cure or even treatment of any one single morbid state, a point on which vivisectors habitually mislead themselves and their pupils by reckless assumptions renewed every year. I am alluding of course to experimental physiologists attached to universities and schools of medicine. The pretentions of many vivisectors, however, go much further. The physiologist I have alluded to not very long ago informed his class that "they must never lose sight of the funda-"mental principle that physiology is the foundation "stone of pathology." He said that in my presence. One instance only will place before the Commission the whole truth respecting the vanity of the above "fundamental principle." What the nature of marsh miasma is the physiologist does not know. What the organic changes are that take place in the organism when inquinated by marsh miasma the physiologist

Mr. A. de Noé Walker.

20 Oct. 1875.

does not know. How quinine acts curatively in intermittent fever generated by the marsh miasma he does not know. The assertion published by Professor Rivière, of Montpellier, is perfectly true. He said "that the discovery of the circulation of the blood had not advanced medicine a single step." What, then, is the use of physiological knowledge to the physician? Knowledge of the healthy functions, as far as they are known, or can be known, enables the physician, not in all but in many cases, to determine the seat of disease. This knowledge must not be underrated. If by comparing the normal functions of, for example, certain portions of the nervous system with the disordered functions of the same parts in a patient, I am enabled to localize the disease in one of the nervous centres, I have attained unto important knowledge, notwithstanding that for the remaining elements of the diagnosis and for the treatment I must leave the dominion of physiology and seek for information elsewhere. I should like now to say something about the second head, as to surgical operations. As regards vivisections made with the object of ascertaining if certain surgical operations are likely to prove successful in the human subject, I have not myself any personal experience; I mean that I have not seen any surgeon perform any such experiments. All the knowledge I possess about them is from reading. Thus I have read of the transplantation of periosteum, of the deligation of arteries, &c., and of the transfusion of blood. The two latter are the most important, and have undoubtedly saved many lives. I beg to observe, however, that vivisections made under this head must be appreciated in a very different way from vivisections performed under the first head; so much so, that in my humble judgment all the legal restriction that I would urge regarding them is this, that they should be performed only by clinical surgeons. The art, and I may add, science, of surgery is nearly perfect, and I believe few, if any, experiments on the lower animals will be necessary to bring it to perfection. The misplacement of many facts I alluded to, earlier in my evidence, consists in this, that all the useful discoveries made under this head are sometimes ignorantly, and sometimes designedly, ascribed to vivisections made by experimental physiologists, whereas they have been suggested, as far as my knowledge goes, by physicians and surgeons in practice. Thus, transfusion is no doubt a vivisection just as bleeding is, but it is not a discovery made by professional vivisectors. A woman, for example, may be flooding, or a man wounded may have lost blood, and the self-evident cause of danger is want of blood. This can hardly be called a discovery. Neither was the remedy, or rather the expedient of transfusing blood into the patient a discovery; it was an invention, and an invention recurred to, not by professional vivisectors, but by men called to the highest scientific calling, I mean men in the actual practice of medicine and surgery. I do not wish to underrate anything or to overrate anything, but the attributing of certain results in order to justify certain abuses is what I have in my mind in mentioning these examples. Regarding vivisections under the third head, made with the object of acquiring manual skill with the view of performing the same operation on the human subject, I have only this knowledge: a surgeon under whom I studied took six goats and triphined the skull of all six, to no purpose in my opinion.

1722. (*Mr. Erichsen.*) Was that in England?—No.

1723. How many years ago was that?—It was when I was a student.

1724. (*Mr. Forster.*) Was any anæsthetic used?—Anæsthetics were not known then.

1725. (*Mr. Huxley.*) What did he do it for; for amusement?—No, he wanted to see the result of triphining the skulls after the animals were dead. If they had recovered he would have killed them, and when they died he made a post-mortem examination of them.

1726. So that it might have been possible that he performed his operation for the sake of knowing what takes place in the human subject?—Certainly. It is fair to state that there is no doubt as to the object of his performing the operation; but I remarked at the time that six were too many, and it would have been quite enough if he had done it on three. Under my fourth head the experiments are very numerous and extremely abused, often aimless and ill conducted by experimenters. I will not enter on that because it is the subject of a separate paper, but the experiments I would desire to bear testimony about are:—(1), on electrophysiology; (2), on the artificial generation of morbid states; (3), on the pathogenetic physiological and toxic effects of certain mineral, vegetable, and animal substances.

1727–8. (*Mr. Forster.*) Have you any special remark on the artificial generation of morbid states?—Yes. On the induction of morbid states much may be said, as these experiments have greatly increased within the last few years. My own individual experience regarding these experiments, with one exception to which I will advert in a few minutes, is limited to inflammatory states caused by caustics, cutting instruments, the insertion of foreign bodies into the tissues, and to the inquination of corrupt animal fluids. Inflammation by chemical and traumatic agents was set up in the joints, and in the transparent cornea of the eye by passing a thread through it, and establishing a seton. These experiments also caused great pain, and the lambs and dogs on which they were performed were unable to rest day or night, and if some ease enabled them occasionally to rest, the experimentor used to exasperate the wounds afresh, and thus made rest impossible. I cannot say whether these experiments have revealed any facts that have led to useful therapeutic results. I wish particularly to declare, however, that if they have, their use will be limited absolutely to cases where the injury has been caused by traumatic or chemical agents, on parts *previously healthy.* This condition, as far as my experience goes, is always ignored by experimental pathologists, and they lecture or write on inflammation so induced just in the same way as if it had all arisen from any one of the many diathetic diseases to which joints are liable. A traumatic lesion, bringing on inflammation and its effects, in the healthy tissues or joint of a dog or lamb, cannot be compared to a disease in the corresponding joint of a human being or other animal, in whom the morbid state has an hereditary or scrofulous origin, and causing a long series of morbid changes, ending in, *e.g.*, "white swelling."

1729. (*Chairman.*) Has your attention been called to any legislative remedies, which you are desirous to recommend for the consideration of the Commission?—Yes; I can answer that question by stating two or three heads which, in my opinion, would meet all the cases that I know of. I would propose first that no person should be allowed to perform experiments on living animals without legal permission from some competent authority. Exceptions should be made, however, in forensic cases when the analyst might find it necessary at once to test suspected matter on some animal. Secondly, the number of animals allowed yearly to each licensed experimentor should be limited. I think if this is not done it will invalidate any other restriction that can possibly be thought of. Without casting a reflection on anybody, I will only say that if I were a licensed vivisector, I might go on all the year, and have persons in my laboratory who are not licensed, and they might perform experiments under me, or nominally under me, and the number would be excessive. I could bring forward many cases in which ten, twenty, or thirty animals have been subjected to the same experiment and have given in each case the same result; and I consider that a cruel abuse of power. The third provision would be this: that every licensed experimentor should send in every year to the same competent

Mr. A. de Noé Walker.

20 Oct. 1875.

authority two returns; one showing the nature of the experiments he intends to perform; the other the results obtained by these experiments. The first would prevent a great many useless experiments, either because they are quite unnecessary, many having been probably performed before, or because they might be aimless or useless. The second return would test the ability and humanity of the experimentor, and the utility of the experiments, which, if published, could at least be referred to by other experimentors. This return should also show whether anæsthetics were used, how long the animal remained insensible, and how long it was kept alive, this last item should not be omitted. There are very great abuses, I think, on that head; animals to my knowledge have been kept alive when they might have been destroyed long before. I will give you an instance of that. In looking over my papers, notes, and memoranda, made while attending lectures, I have found a small diagram proving that which I have always asserted, that experimental physiologists attached to schools of medicine have been to my knowledge guilty of great abuse of power. The sketch represents a frog prepared in this way; the two sciatic nerves are laid bare for about half an inch; the animal is then placed into a small trough containing oil or glycerine and kept *in situ* by nailing its feet; in this state the animals live as long as nature can endure such torture while the experimentor may apply the galvanic current to the nerves, or otherwise "stimulate" them whenever he feels disposed to do so.

1730. (*Mr. Huxley.*) What was the purpose of that experiment?—To preserve the nerves from drying up and withering. I said at the time, "It is a "great abuse of power. There is a great deal of "suffering in nature, but not cruelty;" and I got my usual snubbing. I think also a physiological laboratory ought to be under some sort of proper supervision, because I have seen animals very uncomfortable from want of cleanliness and air, and I have seen frogs kept in closed jars for months till ulcers formed round the mouth and nose; and what pained me most was that they excited no pity, and the person who had charge of them was not at all found fault with, but the animals were exhibited by the professor as showing the evil effects of close confinement, as if similar results were quite a novelty for all the rest of the world.

1731. (*Mr. Hutton.*) Was that in England or abroad?—I am unable to remember at this moment; I can ascertain by referring to my notes. Finally, vivisections for "demonstrations" should be entirely abolished. I am speaking to men of very considerable knowledge of the subject—much more than I have. I do not deny that nature intended the eye to teach the intellect. It would be absurd to do so. Impressions on our minds are very forcibly made by vision, and, therefore, to say that demonstrations do not impress phenomena upon the student is not right; but I think myself that, the moment we have knowledge of the topography of the parts we are describing, the function of those parts is admirably well understood by a verbal description of them, and the amount of suffering is so great, that where knowledge of functions can be attained without demonstrations, they ought to be done away with. For topographical anatomy and the relationship of parts demonstrations are absolutely necessary. For a knowledge of the functions of those parts and systems demonstrations are not necessary. I have got a note here that I should like to read, and that is, that wurari is not, as far as my experience of it goes, an anæsthetic at all, and, therefore, its use for that purpose should be forbidden.

1732. (*Mr. Forster.*) Could you give the ground upon which you form that opinion?—Yes. A dog, for example, inquinated by a dose of wurari, may feel pain. And I judge that he feels in this way:—If, for example, he is petted and spoken to kindly he will try and wag his tail, from which, I suppose, there is still some amount of intelligence and feeling, and if you walk round the room he will follow you with his eyes.

1733. (*Mr. Huxley.*) When he is full of wurari do you mean?—When he is lying down intoxicated with it he will try and wag his tail if you talk to him.

1734. Can a dog full of wurari use a single muscle?—He will try and wag his tail.

1735. Will he when he is fully poisoned with wurari?—Not when he is "fully poisoned," but he will do so under a dose that will paralyse the respiratory organs. I have memoranda in the next room that would clear up the subject very much. Claude Bernard, in 1872, in my presence, and since, has used these words, that "the dog cannot manifest pain, but he feels it." I have got all that Claude Bernard said in the next room. It divides the nervous system in fact, the sentient from the motor. I should like to explain what I meant by saying just now that the legislative means which I suggest would rather promote science than the contrary. A great many experiments are performed in one laboratory which are not known in others, and if there was a return constantly sent in one experimentor would very easily compare his experiments with others, and then the faults of experimentors might be very well detected, and the number of victims very much diminished.

1736. I rather desire to make perfectly clear in my own mind what you mean on some important points. In the first place, I gather from what you have stated that you do not wish to interfere in any way with scientific research. Your opinion, however, is that scientific research might be conducted with a much greater economy of pain than is now the case?—I am sure it could.

1737. But I understand that you do not sympathise with those who hold that such inquiries ought to be put down altogether?—I will answer that question in this way: if you were to ask me, personally my wish would be to see vivisections entirely abolished; but, as is the case with many things that I consider evils, or necessary evils (or if you think the word too hard I will alter it), feeling perfectly satisfied that I cannot ever see them entirely abolished, my object has been for the last two years as much as possible to get vivisection put under legal restrictions.

1738. Then I understood you to say, and this is another point on which I should be glad of some enlightenment, that knowledge of healthy functions does not contain in itself any knowledge which can lead us to therapeutic agents which may help us to cure diseased parts; but from what you said subsequently, I gathered that you meant this that the knowledge of healthy functions does not actually enable you to say what particular drug should be used in any particular case?—Not only what particular drug, but it does not result in any course of treatment.

1739. And I further understood you to say afterwards that you did not by that intend to throw the slightest discredit upon knowledge of healthy functions as the principal instrument of diagnosis?—That is too strongly put for me, "the principal instrument of diagnosis." No one single science whatever can be the principal instrument of diagnosis, except in a few cases, such as, *e.g.*, the detection of sugar in the urine by chemical science. A diagnosis comprehends the seat, the pathology, and etiology of a morbid state. Physiology can only help us, occasionally, to determine the seat of disease in the living subject, and there its use in medicine stops, absolutely. Chemistry and pathology, on the other hand, greatly help us in diagnosing the nature and causes of disease both in the living and in the dead. The localisation of disease, which we are able to attain to by knowledge of the healthy functions, is very much limited to the nervous centres. A knowledge of the functions of the liver would not at all help us in diagnosing disease of the liver.

1740. You do not deny the value of knowledge of healthy functions as a means of diagnosis of disease?—I will repeat what I have said in my statement;

Mr. A. de Noé Walker.

20 Oct. 1875.

I do not wish to put it too strongly. But I do say that the knowledge of the healthy functions of the human body enables us, in some cases, but not in all, and especially in the case of the nervous centres, to localise the seat of the disease. You know better than I that the knowledge of the functions of the kidney, we will say, does not enable us to know the nature of the disease there, but chemistry might. You may know the functions of the bladder perfectly well, but you would not recur to the knowledge of its functions to find out what disease affected it.

1741. Would you say that the knowledge of the structure and functions of the urethra, or the neck of the bladder, was of no use to you in treating diseases of that region?—I am certainly not aware that it is; the anatomy of it is; but I am not aware of the knowledge of any functions of the neck of the bladder being so.

1742. Then if the structures round the neck of the bladder were not contractile, would it be the same thing as if they were?—But that is a case of pathology, I should say.

1743. Of course I need not ask whether you attach great value to the use of the stethoscope?—Yes, certainly.

1744. Or whether you attach weight to certain modifications of the second sounds of the heart?—Certainly.

1745. You base certain conclusions as to the kind of disturbance of the functions of the heart on the modifications of that second sound?—Yes.

1746. Can you tell me whether there is any doubt at present that the cause of the second sound of the heart is the action of the semi-lunar valves at the origin of the aorta?—What I was taught by the physiologist was, that the cause of the second sound is a complex phenomenon, and that it is not only due to the action of the semi-lunar valves of the aorta.

1747. Are you aware of any experiments made on that subject?—No, I am not.

1748. That 25 years ago the whole question was settled by direct experiments, and there was no other way of settling it?—I am not aware of that. The sounds of the heart, as far as I remember back, were not very satisfactorily accounted for.

1749. At the time to which you refer it was a matter of great controversy, for no other reason than because it had not been examined experimentally. It was then examined experimentally, and now it is placed on a certain basis, and it is a matter notorious to physiologists?—I do not profess to be a special physiologist, but I was taught that the sounds of the heart are due to complex causes. What I insist upon, however, is this,—a physician knows the parts involved in causing the first and second sounds of the heart. If a patient consults him in whom the sounds are not physiological, he at once bears in mind the anatomy and physiology of the parts involved in causing the sounds, and is thus often able, at once, to determine the seat of disease. But physiological knowledge cannot lead him any further, absolutely. In order to determine whether the mischief is due to a rheumatic or gouty diathesis, or to some strain of the parts, he leaves physiology altogether, and recurs to other sciences. Sir William Gull has lately published his judgment, that "'the clinical physician knows that the "'phenomena of disease are not explained by the "'phenomena of healthy texture,' nor by the action 'of healthy organs."

1750. I observed that you passed over the whole of that enormous province of human suffering, perhaps the very largest class of all, nervous diseases. I think I understood you to say that your observations did not apply to them at all?—I said that the knowledge of the healthy functions of the human body, more especially in morbid states of the nervous system, was decidedly useful.

1751. So that there your statement as to the absence of any use of knowledge of the healthy functions did not apply?—Do not run away with the idea that I say that the knowledge of the healthy functions of the human body is not of use. I have said that it is.

1752. I wish to bring out the whole meaning of your statement to the members of the Commission, who may not be so familiar with the subject as you are?—I am very glad that that should be done.

1753. So that I think I may take it as your opinion, as much as my own, that anything like rational diagnosis, or any sort of conception of disorders to the nervous system, is entirely based on knowledge of the functions of that system?—No. The only one element of the diagnosis, and the only conception we can form of any one disease of the nervous system that can be based on our knowledge, of the healthy functions is, that it may reveal to us, in most cases, the seat and extent of the morbid state. Nothing more.

1754. Will you tell me any functions of the nervous system that have been ascertained except by experiments. Will you tell me whether the function of nerve in giving rise to the contraction of a muscle has been ascertained by experiments?—Entirely by experiments.

1755. Have not the functions of the sensory nerves been entirely determined by experiments?—Entirely by experiments.

1756. Have not the functions of the spinal cord been entirely determined by experiments?—Yes.

1757. Supposing you were called in to a case of paralysis, and found one side of the man paralysed, could you diagnose the amount of injury that had taken place, without knowledge based on experiments?—It would depend on my knowledge of the nervous system. Comparing the morbid phenomena of my patient with what I know of the healthy functions, I should be able to determine the seat and extent of the injury, not the nature of the injury; not the cause, nor the therapeutic indications. Other sciences would teach me regarding those points.

1758. Although it may be that experimental physiology up to this time has not actually suggested the precise remedies that you ought to employ in a case of disease, do you think that there is any more chance of understanding the nature of disease, unless you know the healthy state of the healthy action, than there is of knowing how to repair a watch if you do not know its structure?—We know the functions, I suppose, of the kidneys tolerably well, as well as any other parts; but my knowledge of the healthy functions of the kidneys will not enable me to diagnose the essential nature of one of the diseases to which the kidneys are liable. It will teach me that the kidneys are disordered, but will not tell me whether there is fatty degeneration.

1759. That is to say, the knowledge of structures has taken you a certain way, but not all the way?—I said just now, when I was speaking on that subject, that I believe myself that the knowledge of the healthy functions of the human body will enable us in many instances, but not all, to localise the seat of the disease, but not to diagnose the nature of that disease, or the cause of it.

1760. Let us take the case of the commonest of all morbid affections, inflammation; have we any knowledge of the minute nature of inflammation, I mean of the actual processes which go on in the tissues, which is the first step towards anything like a rational treatment, except from experimental inquiry?—All our knowledge of the first processes is due to experiments; but if you ask whether that knowledge has revealed any remedial agent, whereby those morbid states can be neutralised, I deny it. This question involves pathology, not physiology.

1761. But seeing that in all cases you cannot hope to deal with a thing rationally unless you know its nature, is it not to be anticipated that a full knowledge of the nature of a process will eventually lead to a rational mode of treating it?—This again regards pathology, not physiology. No doubt pathology sometimes points out, in the clearest way, the one efficient therapeutic indication, but not the therapeutic agent itself. It revealed to us the presence of the acarus scabies, but did not teach us that sulphur could destroy it. "A *full knowledge* of the nature of a process" would be highly important, but are unable to observe the consecutive series of organic changes that occur within our organism during the course of a disease. We talk of a cancerous diathesis, but cannot trace the organic changes ultimately generating a cancerous tumor in the breast.

1762. There is another very important set of diseases, take the case of ringworm for example; I presume that no rational treatment of that was adopted; that the theory of that disease was not understood until it was known that it was a parasite?—They used a good many efficient remedies for it before they knew it was a parasitic disease.

1763. It was sometimes treated with calomel, was it not?—Yes.

1764. Inasmuch as in a case like that the knowledge of the nature of the disease has led to its rational treatment, is it not to be expected that a knowledge, if we could obtain it, of the nature of, we will say, small-pox, may by and bye help us to treat it properly? —My answer to that question is this: if you could attain to the essential nature of what small-pox is, and the organic changes which take place in the human system during, we will say eight days, that amount of knowledge would be most important, but it is almost supernatural.

1765. Are you aware of the fact that within the last ten years such progress, as you are now regarding as supernatural, has been made in regard to sheep-pox, a perfectly analogous disease?—If by that question is meant that they have attained to a knowledge of the organic changes that take place in a sheep affected with sheep-pox, I know nothing about it.

1766. You are not aware then that investigation has shown that that disease is the work of a small organism?—I am perfectly aware of that. What I mean to say is, that the organic changes that that small organism produces in the animal are not known to us.

1767. But the first step to understand the nature of the disease, and therefore to get at a rational treatment of it, is to know what is the cause of the disease? —Etiology is no doubt very important; chiefly, however, to prevent the advent of disease. It seldom indicates a rational treatment of it. I refer you to what I have said about murch miasma, intermittent fever, and quinine.

1768. You think that purely empirical treatment is better than rational treatment, do you?—No; but I deny that the knowledge of the first initial stage of a disease gives you a direct clue to the right treatment of it.

1769. In the case of ringworm, I thought we agreed that knowledge of the disease has been a great help to right treatment of it?—Yes, it has. It indicates that the parasite must be destroyed, but does not teach us what agent could affect that. Sulphur was used long before it was known that scabies was due to the presence of a parasite. Parasitic disease, however, is not the best example to discuss. They involve no, or only slight, organic changes. Kill the parasite, and the disease is cured, just as a surgeon removes a splinter from the soft parts, and cures his patient.

1770. By the rule of thumb you mean?—Science has made as many blunders as anything else that the world has seen. Anything can be defended in the name of science. If you say that blunders have been committed by empiricism, I reply that as many blunders have been committed on the other side. I am not an empiric, although I verify everything by experiment.

1771. Do I rightly understand you to say, as among the measures which you propose, that the experimentor should send in two returns, one of experiments intended to be performed, and the other of the results of experiments performed?—Yes, I did suggest that.

1772. And your object was that somebody should be the judge whether these experiments were necessary, or not?—Yes, that was my object.

Mr. A. de Noé Walker.

20 Oct. 1875.

1773. Has it occurred to you to consider who would be an appropriate somebody to undertake that office?—I am sorry that I am not in a position to reply to you in a satisfactory way. I will, however, suggest that probably no control would be efficient that has not the result of the united judgment and action of a board composed of physiologists, an equal number of physicians, surgeons, and pathologists; and even a chemist might sometimes give valuable suggestions.

1774. But still you incline to institute a sort of board of control for scientific experimentation?—Yes, on every kind of experiments on living animals.

1775. (*Mr. Erichsen.*) There are two or three points in your evidence which I should like cleared up. One is this: if I understand rightly, you seem to draw a distinction between pure physiologists or biologists and practical medical men?—A very great distinction.

1776. You mean, I suppose, that there is a class of men who are devoted now to the study of the structure of animals and the functions of their organs, quite irrespective of medical practice?—Yes.

1777. But it is not the business of those men in the study of the healthy organisms, to discover new methods of treatment, or to devise new plans of operation for instance; their business is simply to discover the actions of the bodies of animals in the healthy state?—And it would be very important if they kept to that, but my teachers always misled me for some years by saying that the knowledge of the healthy functions which they were teaching us was to form the basis of therapeutics, and of pathology.

1778. And is it the fact that among medical practitioners there are many men very distinguished in practice who never performed any experiments?—A great many.

1779. One of those gentlemen we have had before us, and in answer to a question of mine, he stated that he was greatly indebted in his practice to the experiments of the physiologists?—Did he specify what advantages he had gained from them, may I ask?

1780. He only stated it generally?—Then in my estimation it is worth nothing; we may quite agree or totally disagree. If, as Professor Huxley was endeavouring to establish, these were of use for localising disease, then he was right. If he went beyond that, in my estimation, he was thoroughly mistaken.

1781. There was another point on which you made a statement somewhat at variance with what we have formerly heard, that is with regard to the influence of experiments on therapeutics. There is a disease called angina pectoris, which has been beyond the reach of medical science, and a remedy for it has now been discovered called nitrite of amyl, and Dr. Brunton was led to the application of that drug to angina pectoris by experiments on living animals, and finding that nitrite of amyl produced dilatation of the arteries in them. That is a direct application of a therapeutic experiment to medical practice, is it not? —If the doctor found out from the action of that agent, that it was a remedy for angina pectoris simply from seeing that it dilated the arteries it was a happy guess.

1782. He was led to that inference by seeing the way in which it acted on the arteries of living animals? —We do not know what angina pectoris consists of, and therefore I do not see how he could have been rationally led to that conclusion. The tendency in the medical profession is, when any agent has an elective affinity for a particular organ to try it for several of the diseases of that organ. But I am far from wishing to depreciate the experiment. I believe the specific use of every drug can be known from its action on the healthy organs and tissues.

1783. Then there were a series of experiments performed by Majendie which have a very close bearing on this point. It was supposed before those experiments were made that an animal could live and thrive upon a simple substance such as gelatine, and Majendie, Mr. *A. de Noé Walker.*

20 Oct. 1875.

by direct therapeutic or diatetic experiments, found that the animal would starve under such a system, and that certain diseases were set up in consequence?—Yes.

1784. That I take it is, one may consider, the direct application of a therapeutic or rather a dietetic experiment to medical practice. Since that time we know that it is useless to keep a patient upon one kind of food, and that knowledge is based upon those experiments?—Yes. I was present when Majendie fed his turkeys for 40 days on albumen, and they all died of inanition. You must call that a diatetic, and not a therapeutic experiment.

1785. It is comparatively of late years that the application of experiments to pathology, I mean in the artificial induction of diseases, has sprung up?—Yes.

1786. So that it would be scarcely reasonable to expect that any great results should have been arrived at yet?—No, scarcely fair.

1787. But I suppose we may take it as a fact in pathology that we have come to a complete end of the ordinary naked eye dead house pathology?—Certainly.

1788. And that if we do advance in pathological knowledge for the future it must be through the means of the microscope on the one hand, and pathological experiments on the other?—Yes.

1789. Then there was another statement which you made; I do not know whether you gave it as your own opinion, but you said it was the opinion of another gentleman, Rivière, that the knowledge of the circulation of the blood had had no influence whatever upon medicine?—He said medicine, he ought to have said therapeutics, and I agree with him perfectly.

1790. Did he include surgery?—No; I do not think he could have meant to apply that to surgery at all.

1791. With regard to that experiment of trephining the skulls of six goats, it is something so entirely novel to me that I have a difficulty in knowing what could have been meant by such a procedure?—As far as I could make out, it was done by the experimentor partly to accustom his hand to the use of the instrument, and partly to see whether the goats would recover, and then to destroy them, and to see what nature had done in the process of healing.

1792. That experiment was done abroad, not in England?—Yes; the man is dead who performed it.

1793. You mentioned, amongst the various reasons why experiments were done, the one of acquiring manual dexterity. To your knowledge is that ever done in this country?—I am not aware of its ever having been done in this country. I think it is done in America; I may say that Gooch excised part of a rib of a dog to see whether he thought the corresponding operation could be performed on the human subject.

1794. That was not with the view of acquiring manual dexterity?—No.

1795. That, to your knowledge, is never done here?—No, never.

1796. (*Mr. Hutton.*) You were stating that your object in appointing a kind of inspector of experiments of this sort would be to see whether the experiments were in themselves useful; you did not at all mean to deny, I suppose, that useful experiments might be prohibited by even the wisest inspectors in those cases, but your object simply was to suggest that of the two evils, that of inflicting needless pain upon animals and that of losing a scientific discovery, you must choose the less, and that the less was, in your opinion, the loss of scientific knowledge?—I will explain further what I meant. Supposing I send in a list of experiments that I wish to perform, the persons I should appeal to should be in my estimation so competent, so full of knowledge of physiology that they would at once know whether my experiments were original ones or whether they were necessary to confirm experiments previously made. Then, supposing they were to confirm experiments previously made, it would be their duty to point out to me where the previous experiments had been defective, and to instruct me against a repetition of those imperfections. The persons I would appeal to would, so far from being obstructive to science, rather promote it.

1797. However, you would not deny that useful and competent experiments might be prohibited by that means; but you would say that so many useless and incompetent experiments would be prohibited that the balance of advantages would be greatly in favour of some such restrictions?—Certainly they would.

1798. (*Chairman.*) And I understood you to say that the probability was that if the experiment was really useful it would be approved by those to whom you appealed?—Yes; but they would use their discretion in more ways than one.

1799. And therefore that few cases of useful experiments would be likely to be excluded?—Yes.

1800. But that at present a very large number of entirely useless experiments involving great pain are performed by incompetent persons?—Yes; as I hope to prove on another occasion, if the Commission will permit me. I would add this: if I asked permission to institute a series of experiments, not only I say, would the competent authorities I appealed to, point out that the experiments had been done before (if that were the case), and that they were thoroughly unnecessary, but they might point out the deficiency of previous experiments of the same nature, and teach me how to avoid them; and I consider that would be quite in favour of science, and do away with a great number of ill-conducted and painful experiments.

1801. (*Mr. Hutton.*) I suppose you would go further and say that unless a specific object was contemplated the experiment should not be allowed; supposing, for instance, it was merely in the nature of an experiment to see what would happen. Unless you could see a specific scientific object in it such an experiment should be prohibited, you would say, if it were of a very painful kind?—Not only should it be prohibited if of a very painful kind, but every kind of experiment on living animals, if there was not a foregone object in the experiment, should be forbidden. What do you think of pouring half a pint of boiling water into the stomach of a dog, for instance? Or of injecting a quantity of sand into the veins of a dog. What foregone object was there in that?

1802. (*Mr. Huxley.*) Are we to take it as your opinion that eminent physiologists, whose time is valuable, perform such experiments with no object whatever, and for mere wantonness?—My reply is, that a certain number of experiments performed by them, I deem to be wanton cruelty.

1803. In the cases to which you refer did you take pains to inquire from the persons who performed the experiments whether they had any object in view, or not?—I only judged from what they told us during the course of the lecture. I will give you particulars on another occasion.

1804. And during the course of the lecture was an experiment performed and you not told that it had any object or purpose whatever?—Every experiment I refer to was not performed before the students at the lecture, but the experiments were referred to.

1805. And referred to for no purpose are we to understand you to say?—I must postpone my reply to all this to another day.

1806. I wish to be perfectly clear as to what your meaning is. As I understand the matter now it stands thus, that these persons introduced into their lectures for no discernible purpose whatever accounts of experiments which appear to have been excessively cruel; that is so, is it?—Yes; but I will more fully explain my meaning another time.

1807. (*Mr. Hutton.*) Do you mean for no scientific purpose, or for no demonstrative purpose?—For no demonstrative purpose.

1808. Had they no object in view?—I did not mean that; I will refer to those experiments another day.

1809. I did not quite understand what your view was as to demonstrative experiments. You said (I

Mr. A. de N
Walker.

20 Oct. 187

thought very justly) that no one could deny that the eye was a very much more powerful teacher than mere reading could be in such matters; but whether or not you justified experiments by that observation or condemned them, in spite of that observation, I could not quite understand?—What I meant was this, that it is really going against, I was about to say common sense (I say it with deference), to say that the eye was not intended to instruct the mind. If I see certain phenomena evoked in an animal in the theatre I am much more likely to be impressed with everything concerning those phenomena than if I had only read about them; but what I mean is that the knowledge of functions is so easily understood by oral instruction and reading, that I do not consider demonstrations to be either necessary or justifiable; and if it was otherwise, allow me to say that the greatest number of physicians and surgeons in practice would be nearly entirely ignorant of physiology, because since they attended lectures it has made tremendous strides; and since 1868 all the knowledge which I have of modern physiology is from reading, and I find no difficulty in understanding it. You have heard, for example, that there are two sets of roots coming out of the spinal cord. If any one member of this Commission, not having received a medical education, were pointed out on the slate that the spinal cord gave out two roots, and I upon the slate endeavoured to explain the different functions of these two roots, nothing could prevent any member of this Commission understanding thoroughly the functions of those roots.

1810. (*Mr. Forster.*) You stated that you did not think that there was as much of these experiments at home as abroad. Have you any opinion as to whether the experiments which are made in this country are generally made with anæsthetics, or not?—The question of anæsthetics is not so very simple. When an experimentor says, for example, as is said in a very recent publication, that "before and throughout these experiments anæsthetics were used," it is perfectly true; but if by that you choose to understand that while the animal lived and was experimented on, he was throughout insensible, it is the greatest delusion that ever was. I have written a paper upon that very subject. Then with regard to the question of the excess of cruelty in this country, I am bound to say that I am not so competent a judge of what goes on in this country, as I am of what I have seen in foreign laboratories. I chiefly judge from publications, where I see, however, a great excess in the number of the experiments. I would have suspended from rank and pay, as we say in the army, a certain physician at a certain hospital for vivisecting 16 cats, upon which he performed the same experiments, and obtained identical, or nearly identical, results. I do not consider him worthy to be an experimentor at all. I consider that a man who does that ought not to be licensed.

The witness withdrew.

Dr. Lawson Cape, M.D., called in and examined.

Dr. L. Cap
M.D.

1811. (*Chairman.*) You were formerly, I think, in practice in London, were you not?—I was.

1812. You have now retired from practice?—I have.

1813. Are you in communication with the Society for the Abolition of Vivisection?—I have seen Mr. Jesse; I am not a member of that society.

1814. Are you aware that you are desired by them to appear and state your views to the Commission?—No.

1815. Do you consider yourself identified in sentiment with them?—To a certain extent.

1816. You are desirous of stating to us your views on the subject?—I am prepared to do so.

1817. Will you be so good as to state your views?—My views on the point are, that practitioners now and for the last 20 years and more, surgeons and physicians, have taken very good care of the public health without ever having attended anything in the way of vivisection; in the medical schools where they were educated there was no such thing as vivisection.

1818. And you think that the recent introduction of that practice has not been called for by any necessity existing on the part of the public?—Certainly it has not.

1819. Are you of opinion that any legislative measures are called for by the present disposition to extend that practice?—I should deprecate any extension of the practice.

1820. Do you think that it was in former times carried too far?—I have never seen it in England or in Scotland; I was educated at St. Bartholomew's Hospital, and at Edinburgh, and lectured for ten years at St. Thomas's Hospital, and no such thing was heard of as vivisection. At the time I was in Paris for three winters and two summers, they had vivisection, but it was not recognised by the *École de Médicine* or by the authorities at all; it was done on the sly, and they had dogs there for the torsion of arteries and so on.

1821. Is it your opinion that any legislative measures should prohibit experiments altogether, or that they should tolerate it and regulate it?—I do not see how the public would be benefited, as far as medical advance or surgical advance goes, by the practice of vivisection in the medical schools.

1822. Would you allow it anywhere?—It would depend upon the animals. I do not think that in the case of highly organized animals you would be justified in performing vivisection upon them.

1823. Would you allow it in any case?—Well, it must be a strong case.

1824. But suppose it were what you would consider a strong case, would you think it justifiable then?—I could not answer that question unless I had a strong case put before me.

1825. You are not prepared yourself to mention to the Commission any cases in which you would think it justifiable?—No, I am not.

1826. You are not therefore prepared to recommend any set of provisions like that contemplated by Dr. Playfair, by which the Secretary of State should license certain persons to perform such experiments?—I think that license ought to be guarded by certain regulations.

1827. But you would contemplate such a system if it were properly guarded?—If it were properly guarded.

1828. Are you prepared to suggest to the Commission anything that you would consider to be proper security?—Whatever physiological question may have to be decided, if it could be done by experiments upon the lower animals, I should say that that would be preferable to experiments on the higher ones; I mean the more highly organized ones, fully organized ones, like the dog.

1829. By "lower animals" what do you mean?—There are all the phases of animal life below those to which I have referred, and the lower they are the less the nervous system is developed, and the less the pain. I do not think there is much pain, for instance, in a worm to fish with. It has no brain, and I do not think that it suffers, although the popular notion is that it does.

1830. Then you are not prepared to suggest any detailed scheme by which the Commission could propose to regulate a system of experiments on living animals?—I have not had the advantage of reading Dr. Playfair's suggestions about that.

1831. They would empower the Secretary of State to license certain persons to conduct experiments?—I think that is the way it ought to be done.

Dr. L. Cape. M.D.

20 Oct. 1875.

1832. Would you be prepared to recommend that plan for adoption, or would you be prepared to say with the Society for Abolition, that there should be no experiments allowed at all?—No, I should not be prepared to go so far as that.

1833. (*Sir J. B. Karslake.*) May I ask how many years you have been out of practice?—Eight or ten.

1834. I suppose you have not attended to the subject very much since that time?—Well, I may say that I have not attended to it since I was at a medical school.

1835. As I understand, you have never seen any instance of vivisection in England?—Not in England.

1836. (*Mr. Erichsen.*) You said you thought that vivisection was of no utility, so far as the education of medical practitioners was concerned?—As a part of medical education in a medical school I meant.

1837. Are you aware that the physiological laboratories in medical schools have been established, not by the medical schools themselves, but under the direction of the examining and licensing bodies, and of the General Medical Council of Education?—That has not been in my time.

1838. They have been established since your time?—Since my time. I lectured at St. Thomas's from 1837 to 1847, and since that the schools are almost a blank to me.

1839. You have no practical knowledge of the schools since the year 1847, I understand you to say?—Not since the year 1847.

The witness withdrew.

Mr. G. Macilwain, F.R.C.S.

Mr. George Macilwain, F.R.C.S., called in and examined.

1840. (*Chairman.*) You were formerly in practice in London, I think?—Yes.

1841. You have retired from practice for some time, have you not?—Yes, for three or four years; rather more.

1842–3. Have you been in communication on this subject with the Royal Society for the Prevention of Cruelty to Animals?—Yes.

1844. And with the Society for the Abolition of Vivisection?—Yes; I have had communications from them.

1845–6. Will you have the kindness to tell us what is the nature of your acquaintance with the subject; have you yourself ever practised any vivisection?—Yes, I have, in early life. Early in life I was very much associated with Mr. Abernethy, and consequently with the writings of John Hunter; and my studies were based upon what I had read of John Hunter, what I had seen of Mr. Abernethy, and what I had tested by the writings of Lord Bacon; and if anything occurred to me which it appeared to me was not reconcilable with their precepts, I strongly suspected it, and was induced therefore again to sift it with regard to the conclusions which I might have been more or less inclined to draw from it. The result of that was that in about 1836 or 1838 it appeared to me that the best thing that I could do would be to endeavour to inaugurate a more logical and inductive inquiry into medical science. It appeared to me that the state of medical science depended upon the imperfect manner in which it had been investigated; and of course that directed me especially to anything which might be, or which might be conceived to be, a fallacy in its investigation. Amongst these fallacies, and I wish particularly to put it in this way, because I am no anti-cruelty man, or anything of that kind; that is no part of my business. I merely looked at the fallacies in common, and it appeared to me that there were very few greater or in more direct violation of the precepts of inductive philosophy or logical reasoning than the dissection of living animals. I could trace nothing that I thought useful to it. I heard then, as I have heard since, that many things were discovered by vivisection; I can only say that it is not the fact. For instance, I find that the discovery of the circulation of the blood is referred to vivisection. In the first place, any man who knows what the circulation is will see that intrinsically that could not be; you do not want the authority which is suggested to you, because you could not discover the circulation in the living body; I do not see how it is possible to do it. If you had a dead body, then it is so easy to discover the circulation, that it is difficult to understand how it was not done before; because if you inject by the arteries you find that it is returned by the veins. Harvey was a pupil of Fabricius, of Aqua Pendente, and Fabricius discovered the valves in the superficial veins. Of course the blood can only move in one direction; but Fabricius did not see that; Harvey did; and that is the real seed of his discovery. But you see it said every day, and I see medical men say, it was from vivisection, from experiments at least on living animals. Then there is another thing, I would say, I see it stated that John Hunter made experiments on animals. Undoubtedly he did. Now it so happens that I have brought a book here, which I published in 1838, which was the first volume of my work on "Medicine and Surgery—1. Inductive Science." I did not go beyond the first volume, because I found that though it was recommended creditably by the reviews to the "scientific few," the scientific few neither paid me for the expenses of that book, nor for my loss of time. I therefore could not go on with it; it would have been too expensive to me to publish the four volumes. But I observe that in that book I state my objections against physiological investigations, by means of dissecting living animals. Now that book is still in existence. It has been very much complimented by the Americans. One of the first professors in America offered to print it again, at his own expense, and I think that I may with confidence state that fact to this Commission, and put it in their power to put that book before any medical men, or any set of medical men now existing, to see if they can really overthrow one single position that I have taken. Now, as of course my object was truth, I take, not every man who thinks it necessary to cut an animal and say, "You see that that nerve makes that muscle move," or anything of that kind, but I take John Hunter himself. And what did John Hunter do? There is no doubt that he made experiments on animals, but I have it in that book that there was not a single thing that he discovered or did, or a single conclusion that he drew from experiments on animals, that might not be much more clearly proved by the ordinary practice of surgeons. I will give you an instance (and this is a kind of *ex pede Herculem* case) with regard to one class of vivisection. It had been thought that when matter was formed, what we called suppuration, there was a destruction of the part; that is to say, there had been a foregone conclusion without investigation, that the nature of the suppuration was what I have stated. It was John Hunter's object to overthrow that, and therefore he made experiments on animals of this kind. He injected irritating fluids into contact with the mucous membrane, that is the lining of some of the canals of the body, and of course he produced matter; but then why did he not look at the disease which we call empyema? Because there he might have seen matter formed in the chest without any dissolution of solids. Another point in regard to John Hunter is this: they say that his discovery, as they call it, for the relief of aneurism was arrived at by experiments on living animals. Now that is also entirely untrue; but with it there is just that mixture of truth which leads people, who will not study their profession, and who are not accustomed to strict study, to draw wrong conclusions. Now I dare say you all perfectly well know what an aneurism is, but in giving evidence it is important not to suppose anything. An aneurism

Mr. G. Macilwain, F.R.C.S.

20 Oct. 1875.

therefore is a giving way of the internal coat of an artery. There is another form which consists in the enlargement of the artery; but there is an aneurism, which is the ordinary case, which consists in the giving way of the internal coat of the vessel. The blood becomes then propelled against the yielding coat; the blood forms a pulsating tumour, and that is what we call an aneurism. Up to that time I must tell you that the operation on that disease was a very formidable operation, and too frequently fatal. It consisted in opening the sack and tying the artery on both sides of it. This was found to be a very bad operation, frequently attended with fatal consequences. I need not detain you with telling you the process. Now Mr. Hunter said that the cause of that was that the artery was tied in a spot where it was diseased, and that if he tied the artery in a sound part he would most likely find that the thing would do very well. He accordingly did so, and the operation proved successful; and that has been certainly a very desirable and excellent improvement in the practice of surgery. But there was not a single thing with regard to it that he could have discovered in a living animal. Now the thing which has probably caused some unthinking persons to infer that is this. There was a great contest at the time. They said that Mr. Hunter is wrong, and that the arteries were generally diseased. Then Mr. Hunter made an experiment on an animal, that is to say, he tried to make an aneurism. He bared an artery, and he dissected off the coats of the artery, only leaving the internal coat, so as to make it as weak as he could, and then he bound up the wound; but after a time he killed the animal, opened the wound, and found that everything had healed, just as if nothing had been the matter. In fact, he could not make an aneurism, and as animals do not have aneurisms, but only the human subject, it is quite clear that there is not a shadow of shade of evidence that his discovery was the result of experiments on animals.

1847. Your opinion, I gather, is that experiments on living animals do not conduce to the cure of infirmities, whether surgical or medical, in the human frame?—I have a most matured conviction of that.

1848. Is all this set forth at length in the volume that you have been so good as to bring to our notice?—No; not at length.

1849. But I mean at as much length as would be possible for us to take in examination?—Yes; I should think it would.

1850. Have you in any way changed your opinions, or seen any reason to modify them since?—Not the least; on the contrary, everything which I have seen since has convinced me, not merely that physiological investigation by means of dissecting living animals is an inauspicious mode of proceeding, because it violates the first principles of inductive philosophy, as also of logic, but that it actually has led to most serious practical errors. I know of no error in the whole practice of surgery (and now I am obliged to mention myself, which is not a very pleasant thing) which has produced an evil equal to that which I myself have practically corrected, and that is the employment of purgatives after the operation in strangulated hernia.

1851. Has that mistake resulted from experiments on living animals?—Yes; and now I wish to show you that. I must tell you that strangulated hernia was, and is now, a very dangerous disease. The intestine escapes from its natural cavity. It is constricted by the tendinous structure through which it escapes, and the consequence is that the case is a very uncertain one; I have seen a patient escape after days, and I have seen mortification take place within an hour or two; so that it is a case of great gravity. The operation consists of cutting down to the part and enlarging the opening of the tendinous structure and replacing it. Now, of course, it is a very natural anxiety for a man to know whether the bowels have acted, because that is a direct proof that the stricture has been removed, but that led to a most grievous mistake. And now I must go back to the experiments. Mr. Travers made experiments on dogs. His book is entitled "On Injuries of the Intestines and on Strangulated Hernia." He made some experiments on animals, and divided the intestines and sewed up the wound and guts, and did a great many things of that kind, and showed that animals have certainly very great powers of repair under such circumstances. But now the inductive philosophy comes in. He left out some of the most important parts of the subject as regarded the human subject because he never purged these dogs. If he had wanted to carry the analogy close for strangulated hernia he should have placed the dog (even supposing it was feasible to do anything with the dog at all), as nearly as possible under the same circumstances as the human subject. But now mark the difference, and just mark the consequence. He does no such thing; but he goes on to the treatment of strangulated hernia, and he says that after the operation the great thing is to get a discharge from the bowels (now this is true); and the great danger is from the inflammation of the peritonœum, that is the membrane covering the bowels, and lining the interior of the body; and he says that purgatives are the great thing; that if there is no peritonitis, we use purges to prevent it, and if there is peritonitis, then we use purges to cure it. Now you must allow me just to refer to that passage, because this is a matter of extreme consequence. I shall not exaggerate if I tell you that a difference in practice saves in Europe, I should say hundreds of lives every year; and I will show you exactly how it was arrived at, because I did it myself, although it is very difficult to claim anything for oneself. In the same book in which Mr. Travers published these experiments he also published the treatment of strangulated hernia; he gave his directions for the treatment which is exactly that which destroys the patient.

1852. Without putting you to the trouble of reading the quotation, we understand you to say that you mention the case of Mr. Travers's experiments upon animals in regard to strangulated hernia as a proof that such experiments may not only not lead in the right direction, but may be absolutely misleading?—Yes; if you add to that "and the practice he deduced from them." At present you have only my word for this fact. But now here comes a very extraordinary circumstance. Here is the transcript of a lecture, the part I refer to being only a few lines, from a gentleman whose mistake induced me first to write upon that subject, and which has been the means of my having any power of claiming that improvement as my own. I could not get him to refrain from giving purgatives, and the patient died. That same gentleman, Mr. Stanley, of St. Bartholomew's Hospital, in lecturing to his pupils some 20 years afterwards, or more than that, says as follows: That at one time purgatives were employed in these cases, whereas it is now perfectly understood that they ought not to be so employed, and he had himself had bushels from cases of strangulated hernia—cases where the fatal peritonitis was traceable to the purge.

1853. (*Sir J. B. Karslake.*) You practised vivisection many years ago yourself, I understand you to say?—I did a little, but that was very early indeed.

1854. Your view is that vivisection is wholly useless, and worse than useless?—It is; and I beg leave to say this, that I have on several occasions offered in print to take any number of experiments which the profession were desirous of putting in force, or in which they had confidence, with the desire to give them my most respectful consideration.

1855. I understood you to say that if you could be induced to believe that vivisection was absolutely necessary you would not hesitate to practice it merely on the ground of the cruelty which is inflicted on animals?—I do not say so.

1856. You said it was not a question of cruelty, did you not?—I said it had not been with me; but I began like other people making great mistakes, and I have endeavoured to correct them. I wish not to

Mr. G. Macilwain, F.R.C.S.

20 Oct. 1875.

encumber the real facts of the case by anything touching on the moral question.

1857. You wish to confine your evidence to this, that in your judgment vivisection is wholly unnecessary?—But please just let me put it in my own way: I only repudiate vivisection as one of the fallacies in medical investigation; I wish to make that distinction, because it mars the evidence to mix it up with other motives. I hope I do not yield to any man living in what I feel as to what is due to animals, and to the high nature of investigations, but I do not wish such considerations to be mixed up with the facts. I would rather it was supposed that I was wonderfully cruel than I would mar the evidence which I believe stands as evidence which is irrefragable.

1858. (*Chairman.*) What I understand you to say is, that you would not tolerate and regulate vivisection, but you would abolish it altogether?—If you are asking me that as a scientific man, I say most decidedly so; but as a fallacy, it is no business of mine to talk about cruelty. I wish you particularly to understand that; I do not wish to judge anybody; I have got my own feelings on that subject it is true, but it is as a fallacy that I condemn it. I think it is a demonstrable fallacy. I do not even admit that up to the present time it is matter of opinion. I believe I have offered two or three times of late years (I am not strong enough now to do it,) to bring the whole subject before the professional public in a course of lectures, provided only that anybody would pay for the room and the lights. When I say that that is a work of enormous labour, because it involves at all events a slight sketch extending over a couple of thousand years, you may suppose that I am in earnest about the scientific part of it.

1859. And you consider that, so far as the practice of vivisection has been used heretofore, it has not been leading in the right direction, but that it has been misleading the profession?—Most decidedly, I think that is a demonstrable thing; and I think the Americans agree with me, for the book which I have mentioned to you was re-published in America; and in fact after that I exemplified my mode of investigation, or rather I should say Lord Bacon's mode of investigation, by publishing that which was not much read in this country, but the Americans immediately reprinted it.

The witness withdrew.

Adjourned to to-morrow at 2 o'clock.

Thursday, 21st October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

Rev. S. Haughton, M.D.

21 Oct. 1875.

The Rev. SAMUEL HAUGHTON, M.D., called in and examined.

1860. (*Chairman.*) You are a Fellow of Trinity College, Dublin?—Yes.

1861. You are the Medical Registrar of the School of Physic of Trinity College?—Of the School of Physic in the University.

1862. I think that is the largest school in Dublin?—The largest in Ireland.

1863. You are in Holy Orders?—In Priest's Orders.

1864. But you are also Doctor of Medicine?—Yes, I have had a medical education, and am a Doctor of Medicine and a Fellow of the College of Physicians and of the College of Surgeons of Ireland.

1865. You are also, I think, a Doctor of Civil Law of Oxford, and a Fellow of the Royal Society?—Yes.

1866. I think you are honorary secretary of the Royal Zoological Society of Ireland?—Yes.

1867. You have taken an interest I think in the subject which has been referred to us, and I think you had some correspondence with the Royal Society for the Prevention of Cruelty to Animals upon the subject?—Yes; I have taken for many years an active interest in the subject of vivisection, sometimes, in cases where I thought it proper, as a strong advocate for it and a defender of it, and sometimes, where I thought the experiments improper, as an opponent of particular classes of vivisections. If your Lordship will allow me, I think a correspondence that I had at the beginning of this year with Mr. Colam, the Secretary of the Royal Society for the Prevention of Cruelty to Animals, will put my position and views more clearly before you. The document in my hand, I presume, has been before your Lordship already. This was a memorial sent to the Society for the Prevention of Cruelty to Animals, praying them to take certain steps, amongst others to procure parliamentary legislation, and it was this memorial accepted by the Royal Society for the Prevention of Cruelty to Animals that led, I believe, in the first instance to Lord Henniker's bill being brought forward, and afterwards to Dr. Playfair's. It is signed by some of the most distinguished medical authorities in Dublin, and it is signed by myself, and in consequence of my signing that Mr. Colam wrote me a letter which I will read. That memorial is as follows:—
"The practice of vivisection has received of recent
"years enormous extension. Instead of an occasional
"experiment, made by a man of high scientific
"attainments, to determine some important problem
"of physiology, or to test the feasibility of a new
"surgical operation, it has now become the everyday
"exercise of hundreds of physiologists and young
"students of physiology throughout Europe and
"America. In the latter country, lecturers in most
"of the schools employ living animals instead of
"dead for ordinary illustrations; and in Italy one
"physiologist alone has for some years past ex-
"perimented on more than 800 dogs annually. A
"recent correspondence in 'The Spectator' shows
"that many English physiologists contemplate the
"indefinite multiplication of such vivisections; some
"(as Dr. Pye Smith) defending them as illustrations
"of lectures, and some (as Mr. Ray Lankester)
"frankly avowing that one experiment must lead
"to another *ad infinitum*. Every real or supposed
"discovery of one physiologist immediately causes
"the repetition of his experiments by scores of
"students. The most numerous and important of
"these researches being connected with the nervous
"system, the use of complete anæsthetics is practically
"prohibited. Even when employed during an opera-

Rev. S. Haughton, M.D.

21 Oct. 1875.

"tion the effect of an anæsthetic, of course, shortly ceases, and for the completion of the experiment the animal is left to suffer the pain of the laceration to which it has been subjected. Another class of experiments consists in superinducing some special disease, such as alcoholism (tried by M. Magnan on dogs at Norwich) and the peculiar malady arising from eating diseased pork (trichiniasis), superinduced on a number of rabbits in Germany by Dr. Virchow. How far public opinion is becoming deadened to these practices is proved by the frequent recurrence in the newspapers of paragraphs simply alluding to them as matters of scientific interest involving no moral question whatever. One such recently appeared in a highly respectable Review, detailing a French physiologist's efforts, first to drench the veins of dogs with alcohol, and then to produce spontaneous combustion. Such experiments as these, it is needless to remark, cannot be justified as endeavours to mitigate the sufferings of humanity, and are rather to be characterized as gratifications of the 'dilettanteism of discovery.' The recent trial at Norwich has established the fact that, in a public medical congress, and sanctioned by a majority of the members, an experiment was tried which has since been formally pronounced by two of the most eminent surgeons in the kingdom to have been 'cruel and unnecessary.' We have, therefore, too much reason to fear that in laboratories less exposed to the public, and among inconsiderate young students, very much greater abuses take place which call for repression. It is earnestly urged by your memorialists that the great and influential Royal Society for the Prevention of Cruelty to Animals may see fit to undertake the task (which appears strictly to fall within its province) of placing suitable restrictions on this rapidly increasing evil. The vast benefit to the cause of humanity which the Society has in the past half century effected, would, in our humble estimation, remain altogether one-sided and incomplete, if, while brutal carters and ignorant costermongers are brought to punishment for maltreating the animals under their charge, learned and refined gentlemen should be left unquestioned to inflict far more exquisite pain upon still more sensitive creatures, as if the mere allegation of a scientific purpose removed them above all legal or moral responsibility. We therefore beg respectfully to urge on the committee the immediate adoption of such measures as may approve themselves to their judgment as most suitable to promote the end in view, namely, the restriction of vivisection; and we trust that it may not be left to others, who possess neither the wealth nor organization of the Royal Society for the Prevention of Cruelty to Animals, to make such efforts in the same direction as might prove to be in their power. If the committee do us the honour to ask our opinion as to how such a work can be carried on, we beg respectfully to indicate some of the ways which we have had in contemplation in drawing up this memorial. 1st. By the appointment of a sub-committee expressly to deal with the subject, to be called 'the Sub-Committee for the Restriction of Vivisection.' 2nd. By instructing Mr. Colam to undertake as many prosecutions of cases of vivisection, involving severe animal suffering, as may prove to come within the scope of the existing law, and so to bring the matter prominently before the public eye. 3rd. Should it be found that grounds for such prosecutions are rarely to be obtained, owing to the secrecy with which vivisections are usually performed, or that, when undertaken, the state of the law renders them ineffectual, it may then be considered whether a bill should not be introduced into Parliament making the publication of any cruel experiment in a scientific journal or other work a legal ground for the prosecution of the publisher, and thus throw upon the operator the onus of justifying the act. In view of the ambition for scientific notoriety, which may be deemed a not insignificant motive for the performance of many of these experiments, it is believed that this provision would be eminently effective. 4th. If a bill on the subject were found advisable, it might properly contain other provisions, such as,—1st, the prohibition of all painful experiments on animals, except in authorised laboratories, and by registered persons, whose experiments should also be registered as to number, nature, and purpose; 2nd, the absolute prohibition of painful experiments as illustrations of lectures; and, 3rd, the extension to three months of the interval of a single month now allowed by law for the prosecution of cruelty to animals after the commission of the offence. All the provisions of such an Act would of course be carefully weighed by Parliament in debate; and while physiologists would contend for such liberty as they might be enabled to justify to the conscience of the nation, the society would endeavour to obtain security against its abuse." On the 25th February 1875, the following letter was written by Mr. Colam to me. "Sir, on the 25th ult. a memorial was presented to this society, of which the enclosed is a copy, and to which your signature was affixed, as I am informed. A special committee has been engaged since that period in collecting information, and in investigating the allegations of the memorialists relating to the practice of vivisection. They now instruct me to beg of you the great favour of placing before them the data upon which such allegations were made in your memorial, in order that before preparing legislative measures, they may be in possession of ample details should evidence be called for by the Houses of Parliament. Recitals of painful experiments on living animals published in medical journals or in medical works, or references to these, will be invaluable." I declined co-operating in providing evidence. I did not want to be made a detective, for the reasons I now give. My answer was this:—"Trinity College, Dublin, 10th March 1875. Sir, I received your letter of 25th ult., and do not wish my position with regard to the question of vivisection, and the more serious one of pathological experiment to be misunderstood. Both practices in the hands of skilful observers have conferred invaluable benefits on the sciences of medicine and physiology, and I must be distinctly understood to object to their abuse only. The practice of vivisection in physiological laboratories is notorious, but difficult to prove, as even those who object to the abuse of the practice (like myself) will not come forward to give evidence against scientific brethren, who are not so sensitive as to the infliction of pain upon the persons of other animals or men, although very sensitive to pain affecting their own persons. The enclosed prospectus will give you a very significant hint as to the practice of vivisections in physiological laboratories. The University of Dublin, in authorising a practical course of histology and physiology, has expressly prohibited vivisection, and will not recognise the certificates of a school in which it is practised for the purpose of illustrating class lectures, or in which students are permitted to practice it. The true use of vivisection and pathological experiment is for the purpose of original research, and they should be employed most cautiously and with a due sense of responsibility."

I now propose to put in the regulation of the University which is referred to in that letter. It is Regulation No. 40. It is resolved that a three months course of practical instruction be given in physiology and histology, placed under the care of the King's Professors of the Institutes of Medicine, and money is provided for that purpose by the order of the Board, and a note added to the order, "vivisections are strictly prohibited."

Rev. S. Haughton, M.D.

21 Oct. 1875.

1868. Now are those regulations concurred in by the College of Physicians in Dublin ?—Perhaps your Lordship will allow me to explain briefly the nature of the constitution of the School of Physic in the University. The University of Dublin was from the time of Elizabeth a very clerical body, and great difficulties were experienced in forming a School of Physic in it. It was therefore at a very early period associated with the College of Physicians founded by Charles II. There were a number of Acts of Parliament, called School of Physic Acts, passed during the last century, but they are all summed up in one School of Physic Act, which was the last Act but one passed by the Irish Parliament in the year 1800, namely, the 40th of George III., chapter 84, which repeals all preceding Acts, except as to some purposes, and in the 30th of Victoria, chapter 9, called the Amendment of the School of Physic (Ireland) Act. By those two Acts, summing up numbers of Acts that preceded them, the School of Physic is under the joint control of the University of Dublin and the College of Physicians; and the regulations made by either College affecting their professors and part of the school must be submitted under these Acts of Parliament to the other college. They do not require the approval of the other college, but the other college has a veto, and can challenge a visitation, which must be decided by the visitors of the college making the alteration. That has occurred sometimes, and each college in fact watches the other, and when regulations like this are passed, they are laid before the other college, and silence gives consent; if the other college takes no notice, it approves.

1869. Then, in short, the regulation which you have just put in may be taken by us to express the views of the College of Physicians in Ireland, as well as of the University of Dublin ?—Certainly; and I may add what I think much more important than the opinion of any College, the overwhelming opinion of the educated public in Ireland, who are extremely sensitive on this subject,—I mean vivisection for the purpose of teaching classes.

1870. You have mentioned also that this course of lectures is under the direction of a professor ?—Yes, Professor Purser, King's Professor of the Institutes of Medicine.

1871. Are you authorised to state anything on his behalf ?—I state from my own knowledge, as Medical Registrar, and I am authorised by him to state on his authority that practically he feels no difficulty in conducting his instruction in practical physiology and histology subject to this restriction, although individually he would prefer not having the restriction imposed on him.

1872. It is your opinion then that in regard to teaching there ought to be a total prohibition of vivisection ?—Yes, I would advocate that.

1873. Then, with regard to scientific research, what is the opinion which you wish to state ?—With regard to scientific research, it is a more difficult question. The use of vivisection in scientific research cannot be prohibited, but I would have it supervised, and I would use as an analogy for its supervision the corresponding case of human dissections. Before the year 1834, when King William's Anatomy Act was passed, anyone might hire a room and dissect a corpse, and he might, as was done in Edinburgh, receive that corpse warm, and not ask too many questions as to where it came from, which led to the hanging of Burke. When that Act was passed, all the evils of body snatching ceased at once, and I believe that now human dissection goes on quite quietly without causing any shock or any offence. I believe that public opinion on the question of vivisection of animals has now reached such a point that we require a supervision of it similar to that which the Anatomy Act produced in 1834.

1874. Then, with regard to teaching, you would prohibit vivisection altogether, and with regard to scientific research, you would tolerate, but regulate it ?—Yes; and I would give the following four reasons for advocating its supervision. If I could trust the conscientiousness and the common sense, and the *savoir faire* of the physiologists engaged in original research, I would leave it in their hands, but I find I cannot do so for the following reasons :—I believe that a large proportion of the experiments now performed upon animals in England, Scotland, and Ireland are unnecessary and clumsy repetitions of well-known results; that young physiologists in England learn German, and read experiments in German journals, and repeat them then in this country. There is a good deal of that second rate sort of physiological practice going on. All that, I think, requires control. The second reason I would give is that in many experiments which ought to be made, the mode of experimenting is unnecessarily cruel. And I would illustrate that by the case of the experiments made at Norwich in 1874 by Monsieur Magnan, of Paris. The object of the experiments was to show the effects of alcohol and absinthe, I presume, ultimately upon man when taken by the stomach, as we are in the habit of doing. The secretary of the department gave rather a hasty consent to having the experiment made, without much inquiry, and a large number of the medical men who were present at the Medical Association in Norwich, when they heard that these experiments were going on, protested against them. Although there was a majority of persons in the room where the experiments were performed in favour of the experiments, I believe that an overwhelming majority of the members of the association would have prohibited them if they had had an opportunity of expressing an opinion. The experimenting was unnecessarily cruel in its mode, because their object was to ascertain the effects of absinthe and alcohol when taken into the human stomach. If you did not choose to employ a man for the purpose (which, in my opinion, would have been quite allowable and easily done), you should then have employed dogs, and tried the experiment by means of the stomach; you should have given them the medicine by means of the stomach or rectum. Instead of doing that, they opened the femoral vein, and injected alcohol into one dog, and absinthe into another. Experiments of that kind I certainly give my hearty opposition to, and would always do so, because I believe that, though the experiment was an important one to do, it was done with unnecessary cruelty.

1875. (*Sir J. B. Karslake.*) Were the dogs placed under chloroform ?—No, the dogs could not be placed under chloroform for the purposes of such an experiment. Your object in such an experiment is to ascertain the effects of two powerful alkaloids, and the dogs could not have been under anæsthesia for such an experiment; which was an additional reason for giving it to them by the stomach, or employing men. I see by the newspapers that there are upwards of 2,000 citizens of Norwich whose votes can be purchased. I would undertake to purchase a score of them to come and get drunk on alcohol or absinthe if you wanted them. My third reason for supervision is that many of the experiments are undertaken without due deliberation and previous forethought. Perhaps it is scarcely necessary to illustrate that an experiment may be devised without sufficient care, and something that might have been foreseen occurs in the course of the experiment, which renders the whole result *nil*, and all that suffering might have been spared. Physiological experimenters would be greatly aided by some supervision, some kind of committee that would weigh the conditions of the experiments, and see that unnecessary pain was not inflicted. The last and perhaps in some respects the most important reason for supervision, is what I consider the exaggeration of the importance of many of the results. An investigator naturally exaggerates his own hobby, and considers the results more important than the rest of the scientific world will. Now the example I would give of that is the uncertainty of the results of many experiments made on animals being extended to men. The late Doctor Hughes Bennett made one of the most extensive and

Rev. S. Haughton, M.D.

21 Oct. 1875.

interesting series of experiments that ever were made on this very subject of the action of mercury on the liver of dogs, and he arrived at certain conclusions which must of course be accepted by medical men as ultimate facts to go upon if we were called upon to treat sick dogs, but they do not apply to sick men at all. Notwithstanding the publication of these results, there is not a medical man in all Europe or America who has altered his practice in regard to giving blue pill in cases of liver congestion. It is a very interesting illustration of the fact that you cannot argue by analogy from one animal to another. I would give as an illustration of that a case I am familiar with, as the experiments were made by myself. At the time of the Palmer murder attention was directed to the properties of strychnia, and a murder occurring at the same time in Belgium, when Comte de Bocarme, with the connivance, if not with the aid of his wife, murdered her brother with nicotine, led to a number of experiments being made by myself on strychnia and nicotine; and I discovered by experimenting on frogs that I could make a bath of nicotine which would kill a frog in a minute, and another bath of strychnine which would kill another frog in four minutes; but that taking a mixture of nicotine and strychnine, mixed in certain proportions, I produced a bath which the frog could live in for weeks. Those experiments were published by the Royal Irish Academy, and the first application made of them was by a young man who was present at the reading of the paper, who was clinical clerk in the Meath Hospital. He went out and became a practitioner in America, and he had the good fortune to save a sailor's life at Saint Louis, Cincinnati, who had taken a large dose of strychnia in a glass of beer, and whom he cured afterwards by tobacco. Since that, five or six similar cases of cure of poisoning by strychnia have occurred. I went on and extended the experiments to dogs, and was greatly struck with the result; I got no such result in dogs at all. That shows how uncertain *à priori* judgments are in reasoning from analogy. I found in that case that the action of strychnia and nicotine upon frogs was nearer to its action upon men than its action upon dogs was, which is contrary to what you would *à priori* suppose.

1876. (*Chairman.*) I understand you then to object entirely to the use of living animals for the purposes of instruction?—Yes.

1877. Whether under anæsthesia or not?—Yes.

1878. I understand that you would tolerate but regulate the same proceeding in reference to original scientific research?—Following the principle of the Anatomy Act of 1834, because that is an important guide to us in this whole question.

1879. Now have you seen the two bills that were in the last session before the two Houses of Parliament?—I have.

1880. Do you approve of either of those bills, or are you prepared to suggest anything yourself as an improvement upon them?—I do not entirely approve of either of the bills. There is a defect in Lord Henniker's bill, in clause seven, in his definition of vivisection. It is confined to cutting or wounding either with knives or galvanism any living vertebrate animal, or producing in any living vertebrate animal a painful disease. That leaves out of the question the case of the administration of poisons or narcotics, because they can hardly be said to produce diseases. It is a defect in the definition of vivisection. And then I object, in clause four, to the principle of charging 10*l.* for a license for a person to conduct experiments, because the Almighty does not always give brains to men who have 10*l.* in their pocket. I would have the poorest man in the country, if the Almighty had endowed him with the gift of research to advantage, at liberty to use it. And I would leave out details such as that bill goes into about urari, as to which it is very doubtful whether the physiology of them is correct or not; and I would secure such a supervision as would arrange details of that kind.

1881. You would leave the details to the judgment of the supervising body?—Yes. I would charge no fee for vivisecting, and I would include more in "vivisecting;" I make the range of it very general. Those are the only objections that I have to Lord Henniker's bill. Dr. Lyon Playfair's bill I have not considered so carefully; but I have noticed two things that I object to in it. I object to clause four, authorising "the President of the Royal Society, the "Presidents of the Royal Colleges of Surgeons in "London, Edinburgh, or Dublin, the Presidents of "the Colleges of Physicians in London, Edinburgh, "or Dublin, and also a professor of physiology, "medicine, or anatomy in some university in Great "Britain, or recognised by the colleges of surgeons "and physicians aforesaid" to give certificates to a person wanting to vivisect. I have no confidence in those gentlemen at all; they would give their permission or prohibit it according to individual opinions. That would be no control, but would be utterly insufficient. And I am entirely opposed to clause eight, "A license under this Act shall extend to any "person assisting the holder of the license, provided "the person assisting acts in the presence and under "the directions of such holder." That would open the door to vivisection performed by young men who are utterly unfit for the purpose; it would be gradually handed over, like post mortem examinations in a hospital, from the hands of the head man to the hands of the class, and it would introduce the practice of vivisection by students. That would be the inevitable result of it, and I believe that is intended to be the result of it in any medical school, that the person holding the license would really be very lightly responsible for what was done; his mere presence would be sufficient.

1882. Do you approve of the distinction drawn in Dr. Playfair's bill between experiments which do not cause pain, that is, which are made under anæsthesia, and experiments which must necessarily cause pain, and which are made by license from the Secretary of State?—That contemplates, as I understand it, the anæsthetical experiments for class teaching, which I wish entirely to stop.

1883. But with regard to those that are made for the purpose of original scientific research would you be satisfied with that distinction?—No, I would require the controlling power, whatever it is, to order the anæsthesia in cases where they thought fit, and to permit its absence where they thought fit, but I would leave no discretion to the operator.

1884. You would not approve of its being taken out of the operation of the criminal Acts against cruelty if anæsthesia was used?—Most certainly not, because I know the practice is to use the anæsthesia very imperfectly, and when the controlling eye is gone to drop the use of it altogether.

1885. The present law, I think, protects only certain animals, and leaves without protection certain other animals?—Yes, and there is great inconvenience in that.

1886. Then are you prepared to recommend a detailed mode of restriction based upon the view that you have given us, that there should be inspectors as there are under the Anatomy Act of 1834?—That hardly falls under the province of a witness; it is rather for the Commission; I merely threw out the suggestion, as a guide, of the supervision under the Anatomy Act of 1834, which has worked uncommonly well, and it occurs to me that if we availed ourselves of the services of the inspector of anatomy under that Act as one of two inspectors, and let the public appoint another, we should have every guarantee that is necessary. These vivisections will necessarily be always performed in connection with large cities and medical schools. There will always be an inspector of anatomy in such a town as Edinburgh, or any large town, or we can get them appointed if necessary at only a slight expense. In Cork, Galway, and Belfast there is an inspector of anatomy, whose expenses are paid by the price paid for the corpses. If the Society for the Prevention

Rev. S. Haughton, M.D.

21 Oct. 1875.

of Cruelty to Animals would not undertake it, I believe that local zeal would undertake it, and would appoint a colleague to him who should be elected by the town, who would be a lay person, and who would protect the public feeling, which is as much entitled to be considered as the feelings of animals in the question. I believe no difficulty would arise in a machinery of that kind.

1887. (*Lord Winmarleigh.*) The main operator, you think, would not have sufficient control over the young men that were under him, under the provisions of that bill which you have just referred to?—Not only so, but the intention of the clause is that he should have none. The intention of it is deliberately to let the youngsters do the whole thing. It is like post-mortems in a hospital; they are officially made by the medical officer who had charge of the case, but in practice they are made by the youngsters in the hospitals; and there is no harm in that if the responsible person actively supervises.

1888. You do not think that some restrictions might be put upon it so as to enforce a more exact compliance with the law?—In reference to the strong feeling I have of prohibiting students from interfering in such matters, I want to express a strong opinion based upon half a life-time's experience of medical students in dissection rooms and vivisections. Our medical students in Trinity College include some of the best and some of the worst young men in the college, and my experience is that the dissecting-room degrades some characters and elevates others; and knowing that it is a moral trial to any young man to pass through the ordeal of the hospital dead-house and the dissecting-room, that it tries and tests his disposition like the Lydian stone of the ancients, I would shrink with horror from accustoming large classes of young men to the sight of animals under vivisection. I believe that many of them would become cruel and hardened, and would go away and repeat these experiments recklessly, without foresight or forethought; science would gain nothing, and the world would have let loose upon it a set of young devils.

1889. (*Mr. Forster.*) I should like to ask you one question with regard to possible legislation, in order to enable me the better to form an opinion as to whether there should be any, and, if so, what? Both these bills agree so far, that they point to a toleration of vivisection under certain circumstances, that is to say, under circumstances of registered places or registered people; in fact, the license is under certain conditions. An objection is made by some persons to any license of vivisection, and another principle of legislation is suggested, that the Cruelty Act should be strengthened, so as to include all vivisectional experiments, both for domestic animals and for other animals, but with a safeguard that if the operation were proved to be (under certain conditions, which would have to be defined,) really for the purposes of scientific discovery, it should not be an offence. Have you considered that suggestion at all?—I have; and I disapprove of it altogether.

1890. I should be glad to know your reasons for disapproving of it?—My reasons are founded on my practical experience as a frequent prosecutor under Martin's Act. I find an extreme difficulty in getting convictions. Some one has to take the trouble to get the evidence, and to pay the expenses of bringing it forward, and for one man that is punished under Martin's Act, as it exists at present, ten escape. The difficulty of obtaining evidence of cruelty practised upon rats and guinea pigs (which are not under Martin's Act), by vivisection would be infinite, you would get no evidence. For example, in the letter which I just now read I declined to volunteer evidence against scientific brethren who have not the same feeling as myself; and, in the same way, you would find that feeling so strong in others that you could get no evidence.

1891. In the interest of the animals themselves, you would think it better to take the plan of a licensed place or person?—If a Machiavelli was putting forward a plan to promote the suffering of animals, he could not suggest a better one than extending Martin's Act, and leaving the troublesome machinery to work.

1892. You stated that you had no confidence in a mere regulation that experiments should be performed under anæsthetics. Could you give us any further reasons why you think that? I need not tell you that it is a most important part of the matter?—Well, that is notorious amongst physiologists. Unless the thing be inspected, I would not trust to it that complete anæsthesia would be produced. I would not trust the enthusiast who is dissecting to keep it up always as long as it was needed.

1893. We have heard that he would be likely to do it for the sake of the operation itself, because he would perform it with much greater ease under anæsthesia?—If it would facilitate his operation it would, of course, always be used by him, but not always if it would not facilitate it.

1894. Do you think that there are any other experiments besides those which actually could not be made under it in which it would rather interfere with the experiment?—Yes.

1895. What sort of experiments?—Experiments of very great importance and interest connected with the formation of complex chemical compounds in the blood. You always run a risk of disturbing an animal by an anæsthetic; you certainly disturb it by pain, but you further disturb it by an anæsthetic, and the products in the blood differ so from those in health that the case comes under the head, which I have already mentioned, of gross exaggeration of the importance of the result. The conditions of the experiment, both by pain and by anæsthesia in such cases are seriously altered.

1896. I have heard it stated that there is this objection to the use of anæsthetics, viewing it from a scientific point of view, that by the use of the anæsthetic you actually put the animal in a morbid condition?—Yes. If you were looking for secretions in the body, for instance, I would not trust to experiments under anæsthetics.

1897. And that is the reason why you would not allow in teaching experiments to be performed under anæsthetics?—Yes; and also for the reason that they are totally unnecessary in my opinion.

1898. (*Sir J. B. Karslake.*) What was the date of the Regulation in the Medical School of Dublin prohibiting vivisections?—The date of the formation of the practical physiology class, viz., a year and a half ago.

1899. Has Dr. Purser been the lecturer, and the sole lecturer, ever since that regulation existed?—Yes.

1900. Have you had communication with anybody, except Dr. Purser, as to the necessity of vivisections for teaching the classes?—We recognize five extra academical schools in Dublin, and they all accepted this condition, and we receive their certificates.

1901. Have you had communication with any of the lecturers in those other schools besides Dr. Purser whom you have mentioned?—Yes, with the professors in these five extra academical schools.

1902. And are they of opinion that it is sufficient to demonstrate at the lectures without having vivisection?—They are, I believe, of that opinion.

1903. I understood you to say that Dr. Purser was of opinion that that was sufficient, but that at the same time he should prefer vivisection to be allowed?—That is, perhaps, a point of dignity about his position as professor. He has authorized me to state that there is no practical difficulty experienced by him in conducting his teaching under that restriction.

1904. But that he should prefer vivisection to be allowed?—That I presume is only as a matter of dignity about his position as a man conducting original research.

1905. Did he state so?—He said "Personally, I should prefer not to have the restriction." I

Rev. S. Haughton, M.D.

21 Oct. 1875.

presume he meant that he felt himself slightly hurt by the university imposing a restriction.

1906. (*Chairman.*) I do not understand you to say that he wished to conduct vivisection ?—Certainly not; I think he simply meant that he would have preferred that the board should have trusted him.

1907. (*Sir J. B. Karslake.*) That is the extent of his objection, is it ?—Yes, it does not at all mean that he could teach better if the restriction were removed, but that personally he would rather that the board had left it to his own discretion.

1908. Now I understand that you propose that certain officers or inspectors should license every medical practitioner or scientific man who desires to carry on vivisection ?—Well, I can scarcely be said to propose that; I leave that to the Commission. I threw out a suggestion that, working on the lines of the Anatomy Act, you might have a similar machinery for this purpose.

1909. Have you worked that out at all further ?—No, it is not my business.

1910. Does it not occur to you that there is a great deal of difference between the operation of the Anatomy Act and any such Act as you might propose? —I think they might be made to work similarly.

1911. Let me put a case to you *à priori.* I suppose that very few people would think that nicotine would be an antidote to strychnine, yet you established that fact by experiments ?—Yes, I partially established that.

1912. You consider that you have established that by administering nicotine to a person who has taken strychnine you would effect a cure, or all events that it would be an antidote to the poison of the strychnine ?—Yes.

1913. Now supposing a person living at a considerable distance from any centre in which inspectors might reside, a man living at Penzance, for instance, had heard or read of your discovery, or that it might have come to his knowledge, and he was called in to attend a patient who had taken a dose of strychnia, and he was desirous of administering a dose of nicotine, but was not by any means certain of the result, would not your proposal prohibit that man from trying the effect of nicotine taken after strychnia on an animal ?—If you mean with a view to administering it to the patient afterwards, the patient would be dead before the experiment would be over.

1914. In that particular case it would be useless, you mean ?—Perfectly useless, and the dog experimented on would have been killed unnecessarily.

1915. In similar cases, in some cases at all events, might not the necessity arise for a medical practitioner not absolutely licensed to practice vivisection to make an experiment with a view of ascertaining the effect produced by a particular drug upon a poison taken by a patient of his ?—I do not think any hastily devised or badly considered experiment of that kind would be of any use. If a man was going in for a course of investigation, which is a long, laborious, and troublesome thing, he could get the necessary permission to do it; but I do not believe in these hasty experiments done in a hurry.

1916. May I take it that your proposal would be to prohibit, under penalty, any person under any circumstances from trying such experiments unless he was licensed to do so ?—I think so. The machinery I am not competent to suggest, but I think it might be worked through some such machinery as inspectors of anatomy associated with others.

1917. (*Mr. Huxley.*) May I ask in what sense the word "vivisection" is used in that regulation which you read to us of the University, sanctioned by the King and Queen's College of Physicians ?—It does not allow of the performance of experiments upon living animals either with or without anæsthetics, but it does not prohibit the exhibition of experiments on animals freshly killed, in which you can keep up artificial respiration, and a professor is perfectly at liberty to use that if he thinks fit; and you will understand what a range it gives us.

1918. So that supposing that I wish to exhibit Weber's experiment of the influence of the pneumogastric nerve on the heart, I could not do it ?—You could do it under that condition.

1919. What do you believe to be the difference of condition between a frog freshly killed and a frog under the influence of chloroform; do you think that a frog under the influence of chloroform is any more capable of feeling than a frog pithed ?—Certainly not. I think if you take care to keep up the anæthesia, if you did not mutilate the frog to which you applied the anæsthetic, you might let it live again and enjoy a few more months of life. If you pith it you destroy it.

1920. So that in point of fact the King and Queen's College of Physicians, by sanctioning the regulation, have deferred to an outside influence, rather than proceeded on their own sense of the propriety of such experiments ?—I do not say so.

1921. I take it from you that a frog decapitated and a frog under chloroform are in practically the same sort of state; the college says, "You may "operate on the one but you may not the other." What is the reason of that distinction ?—I must refer you to the college for an answer; I am merely a fellow of the college.

1922. (*Chairman.*) But I understood you to say that you, as the Registrar of the University, do not feel a trust that anæsthesia will always be used ?—I would not trust that, and I could not undertake to be always present to see that it was done; it would make my life miserable.

1923. (*Mr. Huxley.*) The object of my question is to show that there is no difference of state between the frog under the one set of conditions and the other, and that therefore there is no reason in the nature of things for prohibiting the one kind of experiments when you do not prohibit the other ?—The difficulty of securing complete anæsthesia during an experiment is a practical difficulty in our way.

1924. You have performed a great many experiments under chloroform; do you find any difficulty yourself in doing that ?—No, because I am most anxious to keep the animal completely under it, and I tell off an assistant for the purpose.

1925. So that supposing it were allowable to perform experiments under chloroform, if any person did honestly endeavour to carry out the provisions of the Act, he would be committing no cruelty, and doing nothing worthy of blame. You are rather assuming that nobody would try honestly to carry out the provisions of the Act ?—No, but that it would be laxly carried out.

1926. It is not necessary to suppose that anyone would violate the Act ?—From what I know of medical schools and medical students, I am of opinion that that would be the result.

1927. You told us that Professor Purser gave a course of instruction in histology and practical physiology ?—Yes.

1928. Of course I need not trouble you about the instruction in histology, as that does not concern us; but would you tell us exactly what his instruction in practical physiology consists in ?—I fancy he is limited by this regulation prohibiting vivisection.

1929. I want to know what the effect of that limitation has been ?—I do not think it has limited him seriously.

1930. Can you tell me exactly what he does teach; —I would rather you asked him himself; I have only a general knowledge; you should ask him these questions.

1931. In fact you cannot tell me of your own knowledge ?—No, except in a general way. My knowledge of the school is executive.

1932. And it is not certain, as things stand then, that anything which I should call instruction in practical physiology is given by him at all ?—It is quite possible that you might consider that the instruction in practical physiology is much limited by this restriction.

Rev. S. Haughton, M.D.

21 Oct. 1875.

1933. Is it not just possible that I might consider that none at all was given?—That depends upon your view of practical physiology.

1934. You said, at least I understood you to say, that no great good had been derived from these experiments regarding the action of calomel on the liver, because the doctors go on giving blue pill just as they did before?—Yes.

1935. Is there not a sort of fallacy involved in that?—You do not believe in doctors or in blue pills; you are a sceptic about doctors.

1936. What I suggest is this, that whatever might be the result of experiments on this question, the doctors probably would not alter their practice, because their practice is purely empirical; they find that giving a man a blue pill does him good, and they call it relieving his liver; but whether it relieves his liver or not, they do not know. Do you not think that the fact to which you allude arises from the circumstance that the practice of physicians in such matters is purely empirical, they have simply observed that giving blue pill under such circumstances does good, and therefore they are not in the least degree affected by the discovery of the true theory?—In either case the experiments on the livers of dogs would be of small value, because, the ultimate object being to apply it to the human body, the experiments have not altered our practice in the slightest degree, and the men who uniformly all over the world maintain that practice are a body of great intelligence; they have read all these experiments, and are able to form an opinion on them, as well as any physiologist. Even supposing a particular theory of the action of mercury on the liver is correct, it still proves that experiments on dogs have done very little for man, because they have not altered the medical practice.

1937. You are a great enthusiast as to Zoological Gardens, and as we all know one of the most valuable and efficient of secretaries of Zoological Gardens; did it ever occur to you that if absolute prohibitions of inflicting pain upon any kind of animal are carried out, you may possibly be prosecuted for keeping a Zoological Garden, shutting up animals, and bringing them into a state of disease as a consequence?—That never occurred to me.

1938. That might happen, might it not?—I think if I was prosecuted in Dublin under an Act for that purpose, I would have influence enough in Dublin to create a riot which would effectually stop all such absurd proceedings.

1939. (*Mr. Hutton.*) Have you formed any opinion of this Manual of Physiology published by four eminent men, Drs. Sanderson, Brunton, Foster, and Klein?—I have the book and have read it up and down, but never thoroughly.

1940. Do you think that its tendency is to introduce the practice of experiments amongst students?—Most unquestionably.

1941. And to spread it very much in this country?—Unquestionably that is the tendency. I have read a good deal of the book; it is a very valuable book.

1942. You have not formed any minute judgment on the particular class of experiments mentioned in it?—No, I have not.

1943. I understand you to be entirely opposed to Dr. Rutherford's view, which he declared quite recently in a lecture at Edinburgh, "that demon-"stration on living animals is absolutely essential "for the purposes of teaching?"—I am entirely opposed to that. I wonder greatly at Dr. Rutherford making such an extraordinary statement.

1944. You believe that the student can be brought up to the point at which he becomes really an accomplished physiologist without witnessing any experiments on living animals?—I believe so, with the condition annexed, which I have explained to Professor Huxley, that he is allowed to experiment on animals just killed.

1945. But with that condition you consider that a man might be brought to the point of an accomplished physiologist, and able to conduct a laboratory himself, without having himself practised on living animals up to that point?—I believe that if he was a person gifted by nature with the capacity for such a thing as original research, in a very short time he would make himself as accomplished as any experimenter. I may illustrate that by a thing that will occur to everybody's knowledge. We never teach students the practice of surgery on living men; we could not allow a student to amputate or cut for stone, but they are taught to practice again and again on the dead body, to tie up the artery, and do everything as if the living man was on the table; and some time ago one of our young students got a high prize in surgery, and was examined for this high prize before a large class; he got very great commendation, and is now high up in the Indian army. He excised an elbow-joint on the dead body, and shortly afterwards, having completed his education and taken out his degree, he performed the same operation on the living subject with as much readiness and coolness as if he had been all his life at it, and yet he had never in his life put a knife into a living man before. Therefore, I believe, in the same way it is not necessary for a student to practice vivisection himself.

1946. (*Mr. Huxley.*) I understand you to limit that remark to persons having decided gifts?—Certainly, I would not allow blockheads of any kind to cut up animals, and too many of them are at it.

1947. (*Mr. Hutton.*) With regard to anæsthesia, is there not extreme difficulty in giving anæsthetics to the lower order of animals without killing them, and so destroying the benefit of the experiment?—Yes, I have tried to produce anæsthesia in lions and tigers, and have completely failed.

1948. And in frogs, for instance?—I would pith them. I would divide the spinal cord, and operate on them.

1949. But can all the operations be performed after the frog is pithed which might be performed under anæsthetics, for the purpose I mean of physiological teaching?—No.

1950. And is it not true that a good many frogs have a great deal to suffer, because it is difficult to give them an anæsthetic without killing them, and therefore the operations are performed on them without anæsthetics?—There are experiments which are wanted to be performed on a frog, where neither pithing it nor anæsthesia would be allowable. I think that pithing (I speak subject to Professor Huxley's correction) would give you the means of making all the experiments that chloroform would; but there are a class of experiments where the pain itself is the subject of research, where neither pithing nor anæsthesia can be allowed, and then the frog must suffer.

1951. Have you ever had occasion to interfere to prevent what you thought useless and needless physiological experiments on living animals?—I have mentioned to the Commission that I took an active part in that direction at Norwich, and I did at Oxford also. In addition to that case at Norwich in the year 1868, at Oxford there were some experiments to be made by Professor Marey, and the question was raised at Oxford as it was at Norwich; but fortunately in Oxford it was decided to refer the matter to a committee, and the committee revised the experiments, in fact introduced practically this very supervision which I advocate. Certain experiments were allowed to be made, and others were prohibited, and everybody was satisfied because the thing had not been left to the discretion of this French experimenter or enthusiast, but had been carefully considered by competent men. If that had been done in Norwich the public would have been spared the shock, for it did cause a great shock; in fact the Frenchman was in danger I think.

1952. In regard to the ethical limits you would put on experiments, would you say that you would require that a real remedial agent should be in

Rev. S. Haughton, M.D.

21 Oct. 1875.

prospect, or would you allow them as a mere addition to knowledge ?—As a student I must believe in every advance made for science, and follow it with the greatest ardour.

1953. But would you limit such experiments by saying that a particular and a probable discovery should be in the mind of the operator at the time of the discovery, a discovery which seemed to him already probable ; that he should already anticipate what he expected or hoped to discover, and not that he should simply perform operations on animals, as he would on minerals or vegetables, with the vague hope of discovery ?—I have endeavoured to explain all that in what I said about foreknowledge and preconsideration of the whole question. No man is fit to be in the army of science who makes an experiment at random. He must, whether operating on brute nature or on organic nature, have in his mind's eye some clear thing, whether right or wrong, that he hopes to prove or disprove. And I would prohibit any man who had not such an object from making such an experiment at all ; he ought to be dismissed.

1954. Now these operations on biliary fistula, for example, of which we have heard so much, appear to me to open a great many more questions than they supply answers to, giving only results of the vaguest kind. Would you exclude them ? For instance, I do not know whether you have read the account of the operations on cats in St. Bartholomew's Hospital ?—I voted for the grant to be given to Professor Hughes Bennett for those experiments, because I believed that they had a definite intelligent object in view, and that it was worth inquiring into ; but I was disappointed at the smallness of the result. That we cannot help. I merely instance those experiments, not to say that I disapprove of them, but I think that their importance was exaggerated by myself and others before they were made, and the result was very small.—*Parturiunt montes ; nascetur ridiculus mus.*

1955. (*Mr. Huxley.*) As a practical investigator in science, may I ask you is it not often the case that getting no result is getting a very great result. You have decided at all events that a particular agent does nothing ?—In the case of the experiments on the liver of the dog, that result was very small ; but cases might occur in which a negative result would be very important.

1956. (*Mr. Hutton.*) Still supposing that the result opens up many more questions than it supplies answers to, would you be prepared to allow experiments to go on, as Mr. Ray Lankester said, in geometrical progression as in any other experimental science ?—I would, under proper supervision.

1957. That makes your limitation a very slight one, surely, upon this class of experiments. I did not fully understand you whether you would leave it at the discretion of the inspector, the inspector being an accomplished physiologist, whether or not to allow any vivisection ?—No, I would not set a thief to watch a thief ; I would not set a physiologist to allow another physiologist to go to work ; I would have a bonâ fide inspection. The difficulty is to get that. The public must be represented on it ; and I doubt if an inspection by less than three competent persons would have the confidence of the public. A single inspector out of laxity might be persuaded to give permission.

1958. But the representative of the public would have the power to refuse, I suppose ?—Yes, I suppose so.

1959. And the representative of the public would be very likely to refuse if he thought that the experiments were not of a class likely to do good to man ?—I think very likely he would, and very proper that he should, because I consider that the general sentiment among educated people outside is to be considered as well as the advance of science.

1960. That I think limits the answer that you gave me before, that you would allow any vivisectional experiments in the pursuit of science ?—Subject always to this enlightened control in which public opinion would be fully represented. How to provide that I think is the difficulty ; but I have no doubt the Commission will see their way to it. I might be allowed to say that there is a great deal of nonsense talked in the name of original research. It seems to be rapidly taking the same place in the creed of philosophers that the doctrine of original sin did amongst theologians. By putting a man to make a set of experiments you cannot make him produce results unless he is born into the world with the intellect and the ability that nature gives for such results. No amount of training will make a man an original observer. It is a case of *poeta nascitur non fit*, and I reiterate that in no science is the abuse of the idea of original research greater than in physiology. Every person, second or fifth rate physiologist, sets to work to make original researches, and they are not competent for it. I think that public opinion ought to be brought more fully to bear upon that, and to see whether the objects of this research are as important as their professors say they are.

1961. And that makes you less anxious about the fear of strangling original research ?—If you were to strangle nine-tenths you will do no harm, if you leave the one-tenth that nature meant to go on.

1962. (*Chairman.*) You have not come prepared to detail proposals to the Commission, not regarding that as your province ?—No.

1963. But you are prepared to say that experiments on living animals should not be tolerated at all for the purpose of teaching ?—I am.

1964. But that for the purpose of original research they ought to be tolerated, but regulated ?—Yes.

1965. That that regulation should be in order to take care that the vivisection is only done by competent persons ?—Yes.

1966. That it should only be done for an adequate object, previously well considered ?—Yes.

1967. Everything which leads up to knowledge being arrived at otherwise than by painful experiments, and nothing left to painful experiments except that which can only be arrived at in that way ?—Yes.

1968. That this should be done under a supervision which it has occurred to you might have an analogy to the arrangements of the Anatomy Act ?—Or might be based upon them, making that inspector one of the inspectors for this purpose.

1969. That the proceedings of all persons so engaged should at all times be subject to the influence of public opinion ?—I wish to express that opinion very strongly, that this control should be partly under the direct influence of public opinion.

1970. So that the legislature might know from time to time what was going on, and whether any further restrictions or limitations might be necessary ?—Yes.

1971. (*Mr. Forster.*) Referring to the questions asked by Professor Huxley with regard to Professor Purser's teaching, let me ask, do you or do you not consider that by being unable to perform vivisectional experiments in teaching he was prevented from carrying out fully what ought to be his object as a teacher ?—I do not think so, most certainly, because with the condition that I mentioned to Professor Huxley, of his having it in his power to use recently killed animals, I believe that he can teach everything that practically is necessary. That of course is only my own opinion ; Professor Huxley or Professor Purser might have a different opinion.

1972. Sir John Karslake put to you the case of a practitioner in a secluded part of the country having a man who had taken poison brought before him, and thinking it necessary to try some experiments with regard to antidotes. You replied that it would be doubtful whether that would be useful, because the poison might take speedy effect ?—It would be certain to be useless.

1973. But do not you think that a case of possible utility might be met by a clause in any bill which

Rev. S. Haughton, M.D.

21 Oct. 1875.

would prevent a man being punished who might try experiments solely in the cases of patients who had taken poison ?—I do not think such an experiment would be at all necessary. Where any accident of that kind occurs, if a man knows enough about it to know that a certain thing is an antidote, he will have at hand the details of doses and all that is necessary to counteract that poison, and he could not possibly set to work making experiments on it. It was quite an imaginary case.

1974. (*Chairman.*) If you had been yourself poisoned you would not like to be treated, would you, by a man who knew nothing except from experiments which he made in the interval himself ?—Certainly not, I should be dead in the interval. It is a purely imaginary case.

The witness withdrew.

Mr. A. H. Garrod.

Mr. Alfred Henry Garrod called in and examined.

1975. (*Chairman.*) You are Prosector to the Zoological Society of London ?—I am.

1976. Will you explain to us what the word "Prosector" means ?—The appointment is one which deals only with dead animals. Those animals that die at the Zoological Society's gardens pass through my hands, chiefly for zoological purposes, also for pathological purposes; but I have, in connexion with other appointments, opportunities of performing experiments in physiology, which are rather according to my wishes. I prosecute experiments for my own instruction.

1977. For scientific purposes do you mean ?—For scientific investigation.

1978. Is it your practice to perform them under anæsthetics ?—It is my practice always to employ anæsthetics so far as to produce complete anæsthesia.

1979. Do we understand that all the operations which you perform on living animals are performed when the animals are in such a state that they feel no pain whatever ?—I have every reason to believe that they feel no pain whatever.

1980. Do you approve of the unlimited toleration of the practice of experiments upon living animals, or do you suggest any, and if so what, limitations ?—I approve of the entire absence of limitation as regards the employment of vivisectional experiments in those cases in which original investigations are being performed by any man who is at all competent from physiological knowledge to undertake the operation; but with regard to the employment of vivisectional demonstrations for purely educational purposes, I have a personal prejudice, which I think may be more instinctive than otherwise, against looking on at demonstrational educational vivisectional experiments.

1981. Do I rightly understand you to say that you think in the hands of competent persons, original research should be left unfettered ?—I think entirely unfettered.

1982. In the hands of incompetent persons I suppose vivisection should be prohibited ?—I have never had an opportunity of witnessing any incompetent person attempting anything vivisectional of importance, so that I cannot feel that any restriction is required in that direction; because I think that the existing law with regard to cruelty to animals would include all the cases.

1983. Are you aware that animals like those in the Zoological Gardens are not within the Act for the prevention of cruelty ?—I suppose that is the case.

1984. How do you suppose that the existing Acts would operate sufficiently to protect those animals ?—I think that vivisectional experiments would be undertaken by hardly any men, of their own accord, without rapidly producing such experience in the individuals trying them as would justify their prosecution of those experiments.

1985. Your opinion then is, that although a person is not competent to perform such experiments to begin with, he becomes competent quickly, so that there is no need of restricting him ?—I think that two or three experiments will render persons competent to perform the experiments, or that if they feel then that they are not competent to go on, they will cease of their own accord.

1986. But with regard to demonstration for educational purposes, you would prohibit vivisection with that object ?—I think that for educational purposes quite enough can be taught without the employment of demonstrations by vivisection, and that a perfect understanding to that effect would be very beneficial to the country.

1987. But now are you seriously of opinion that a person who is incompetent to begin experiments on living animals, will become competent to perform such experiments after a few trials ?—I cannot believe that anyone who is so uneducated as not to gain rapidly the power of making such experiments would prosecute vivisectional experiments for any length of time, any more than any person would frequently torture a cat by vivisectional experiments if he is an educated individual.

1988. But suppose that he is uneducated ?—That is beyond the limits of my experience altogether. I do not believe that uneducated people would practise systematic vivisection; there is nothing inherently attractive in vivisection to the majority of human beings.

1989. Do you believe that there is no wanton cruelty at all in regard to vivisection, either in this or in other countries ?—As far as vivisectional demonstrations for educational purposes are concerned, any number of those in foreign countries, and perhaps in this country, would be beyond what I should approve of; but otherwise I do not think that there is any barbarism carried on.

1990. In any country ?—I think that vivisectional surgical operations are objectionable, and I know that they were conducted on a large scale in France some years ago.

1991. But as far as original research is concerned, you have a thorough conviction that there is nothing in this country which would, and nothing in any other country which, if adopted in this country, would be a fit subject of legislative interference ?—I quite think that there is no legislative interference required for that.

1992. (*Mr. Huxley.*) I should like to ask you one question about the employment of vivisectional experiments in education; are you speaking now of general education or special physiological education ?—My remarks referred to the education of classes in special physiology.

1993. That is to say, if I understand you, you do not think it requisite that a student devoting himself to physiology should have any practical instruction ?—I think in regard to vivisection that a student who could make any use of the physiological instruction he is receiving by it, could gain almost all the information he required without any special vivisectional operations being conducted by himself, or in his presence.

1994. By vivisection do you mean merely experiments on living animals while they are in a condition to feel, or do you include under that head experiments on animals pithed or decapitated, or under the influence of chloroform ?—I do not include experiments on animals pithed or decapitated, but I mean experiments on animals under the influence of anæsthetics. I should include them, because I know that when an experiment is being conducted before an audience, there are many causes which would make an operator, from slight nervousness, or otherwise, pay less respect to the animal than might be desirable, and than would be most likely the case during the pursuit of original research.

Mr. A. H. Garrod.

21 Oct. 1875.

1995. I am thinking, not of experiments made before a class of ordinary medical students, but of the kind of practical teaching which might go on in a physiological laboratory, practical instruction running *pari passu* with the instruction of a professor, in the same way as practical instruction goes on in a chemical laboratory *pari passu* with the instruction of a professor. Have you any objection to that kind of use of vivisection?—It seems to me hardly necessary that everyone should repeat the important fundamental physiological experiments for himself, because I think, as a rule, the descriptions in text books are sufficiently good to render any student of comparative intelligence fully able to understand what he would learn from the actual experiments.

1996. You have gone through a course of thorough instruction in chemistry, I think?—I have.

1997. Then I need not remind you that every student, it he is to become a chemist, not only attends the lectures of the professor, and hears the description of the properties of oxygen and hydrogen, and so forth, but is absolutely made to spend a great deal of time in the laboratory in studying the properties of these elementary bodies, which are as well known as anything can be, for himself; and any chemist to whom you suggested that a student of chemistry need not go through such a training would laugh you to scorn. I think you will agree with me in that?—Yes.

1998. Do you think that there is such a great difference between physiology and chemistry that mere description is not sufficient to give you a competent idea of the comparatively simple phenomena of chemistry, while it is sufficient to give you a competent idea of the complex phenomena of physiology?—You refer to chemistry being taught practically, but let me say that a subject quite as large, namely, surgery, is taught by purely theoretical lectures, because it is found impossible, on account of the nature of the operations conducted, that it should be otherwise. That has to be taught by theoretical means only. The student of surgery no doubt does suffer from not being able to operate on the human body, but he has to make up for that on account of the disadvantages connected with practical surgery on the living body by extra study. I think the disadvantages connected with practical vivisection in physiological experiments require the student to study so much more to get a thorough grasp of his subject, and I think that that extra study would make up for the deficiency, just the same as in surgery, in the practical operation.

1999. But is there not this very great difference between the two cases, that the surgeon is able by his study of anatomy beforehand thoroughly to know all the relations of the parts, and the only thing that he has to learn is that comparatively small difference which they present in the dead and the living state; whereas, in the case of physiology, I am sure I need not tell you that no man could obtain the slightest conception of the operation of a living muscle by merely looking at it in the dead state?—I quite agree with those remarks, but I think that the difference between the operation of cutting a dead body, which the ordinary student performs, and his first operation on the living body has something more in it than the difference of the appearance of the tissues, and that the responsibility connected with the whole subject produces a difference of sensation in the operator. So in physiology I think no doubt it is necessary to study the phenomena of living muscles, that as far as original investigation is concerned I think is quite correct, but for the demonstration of things already well known, I think that is not more necessary than for the demonstration of surgical operations.

2000. Let me ask you whether there is anything which is much easier to understand, as a mere matter to talk of, than the circulation of the blood in the capillaries?—It is very easy.

2001. And is there anything in which the idea present in the mind, after talking of it, is more different from what you get by your seeing it, than it is in that case when you have seen the circulation in a frog's foot?—I do not realise the difference as being so great.

2002. A distinguished witness who appeared before this Commission some time ago (and, by the way, an opponent on the whole of vivisection), was so much impressed by the difference between seeing a physiological phenomenon and merely talking about it, that I think he rather regretted he had not brought a fish's heart to show in pulsation. His opinion was that the difference between merely talking about the movement of the heart in circulation and seeing it was so great. I understand you not to agree with that?—I think a student looking at the heart for five minutes would learn very much less than he would by reading for the same length of time as to the circulation.

2003. But suppose he had prepared himself before by reading, and then studied the phenomena as they occurred in nature, would he not have a grip of them such as he could not have by any conceivable reading?—My experience is not quite in that direction.

2004. (*Mr. Erichsen.*) Am I correct in understanding that you do not object to certain kinds of experiments for demonstrational purposes, those, for instance, in which the animal is pithed?—I have not the least objection to demonstration where the animal is pithed or decapitated.

2005. But only where it is anæsthetised?—Only where it is in a condition from which it can return to the normal condition afterwards.

2006. You have had a good deal of experience in anæsthetising animals, I conclude, from what you said in the early part of your evidence?—I have anæsthetised a great many animals.

2007. Have you ever found any practical difficulty in anæsthetising animals so as to render them perfectly, so far as you can judge, insensible to pain?—I have had on more than one occasion to transfer one method of operation to another. For instance in giving chloral to a ruminant animal, the same dose that would anæthetise a horse or donkey will not anæsthetise a ruminant animal, and I have had to transfer my anæsthetic to vapours, but I have found no real difficulty.

2008. By employing the proper anæsthetic according to the animal you deal with, you have found no difficulty, employing one anæsthetic for one animal and another for another?—None.

2009. Have you been in the habit of anæsthetising the larger animals; you have mentioned the ruminant animals?—I have anæsthetised on one occasion the largest ruminant animal that ever lived, the giraffe, perfectly.

2010. Are any pathological experiments conducted at the Zoological Society's Gardens?—No, there is no systematic pathological experimentation; the Society has no object in view in conducting anything of the kind.

2011. The Society itself, I take it, does conduct a gigantic pathological experiment?—You mean in keeping the animals there at all?

2012. And in engendering tuberculosis; they almost all die of tubercule, do they not?—No; I do not think 40 per cent.

2013. But as many as 40 per cent. do you think?—Not so many; the larger number die from conditions which it is not possible to find any reason for; tubercule is the most common disease from which they do die.

2014. (*Sir J. B. Karslake.*) That is to say taken all round?—Taken all round more animals die of tubercle than anything else.

2015. The monkeys particularly die of tubercle, do they not?—The old world monkeys.

2016. (*Mr. Erichsen.*) That being generated by the conditions in which they are placed?—Undoubtedly.

2017. (*Lord Winmarleigh.*) Have you been able to form any judgment of the difference between the length of life of an animal confined in the Zoological

Mr. A. H. Garrod.

21 Oct. 1875.

Gardens, and an animal at large in its natural state?—Only with regard to those animals which are accustomed to be domesticated. Our cattle and deer live for a considerable length of time, quite as long as they are known to have lived when feeding in fields. We have had oxen live for 25 years, for instance, and that is a good age.

2018. As to lions and tigers is that the case?—I should say the tendency for them is rather to live shorter lives when they are confined.

2019. (*Chairman.*) But then they are free from the accidents to which they would be exposed in a state of nature?—They are free from accidents, but they suffer from plethora or want of exercise.

2020. (*Mr. Hutton.*) May we assume that you were not obliged to go through a practical physiological laboratory yourself before completing your education?—I was not.

2021. In fact you completed your education without any experiments on living animals at all, as I understand?—Exactly.

2022. (*Mr. Forster.*) You have had great experience in the administration of anæsthetics; have you formed any opinion on this matter as to whether it is or is not more difficult to be quite sure that the anæsthetics are completely administered to an animal, than you would be if they were administered to a human being?—I have never found any difficulty in that way. Perfect quiet on the part of the animal during the performance of an important skin section, for instance, I always take as a test of complete anæsthesia.

2023. But there are cases which we have heard of, in which a man or a woman has had anæsthetics administered, and during the operation they have groaned or shrieked, but afterwards have declared that they suffered no pain. That of course is a means of obtaining knowledge that would not apply to an animal?—I think you find that animals indicate to anyone watching them, quite sufficiently by sounds, whether or not they are in pain. They groan just in the same way that a human being does, they emit a kind of groan which is quite symptomatic of pain. I always take it for such.

2024. The meaning of my question is this, that there might be complete anæsthesia with a human being, and yet he might groan during the operation, but you find out from him afterwards whether the anæsthesia had been complete or not; but as in the case of animals you could not find out afterwards whether it had been complete or not, you would think that it was necessary to produce perfect quiet before you had done enough for an animal?—That is my general practice.

2025. (*Lord Winmarleigh.*) Did I rightly understand you to say that during your practice animals have groaned under anæsthesia?—The symptoms for repeating a dose of chloroform would be the least indication to kick, just a movement, a slight raising of the leg, or a slight flinching of the open eye, or the slightest noise from the mouth, not connected with respiration.

2026. But an animal when it is in full vigour and suffers pain does groan, does it not?—I think it is not at all difficult to recognize in a horse or an ox the least pain.

2027. (*Mr. Hutton.*) Have you made any experiments of that kind on frogs?—I have very seldom anæsthetised them with chloroform. I have given them ether frequently, and found that they have remained under it a very considerable time.

2028. But not chloroform?—I have not given them chloroform.

The witness withdrew.

F. W. Pavy, M.D., F.R.S., and P. H. Pye-Smith, B.A., M.D.

FREDERICK WILLIAM PAVY, M.D., F.R.S., and PHILLIP HENRY PYE-SMITH, B.A., M.D., called in and examined.

2029. (*Chairman to Dr. Pavy.*) You are physician at Guy's Hospital and lecturer on physiology?—Yes.

2030. In your capacity of physician and physiologist at Guy's Hospital you have considerable experience, no doubt, on the subject which is referred to this Commission?—I have.

2031. Are you of opinion that the practice of experimenting on living animals is one which subjects living animals in this country to great suffering?—I may say to an almost insignificant amount of suffering. Experiments need not be performed to submit animals to any appreciable amount of suffering, that is to say, the generality of experiments.

2032. You mean owing to the application of anæsthetics?—Yes.

2033. And I understand you to say, that so far as Guy's Hospital is concerned, anæsthetics are always employed?—I have lectured for 20 years on physiology at Guy's Hospital; I am for the 20th year, I would say, lecturing on the subject now; and I believe I was the first person in London to commence using experiments in illustration of physiological lectures, and I have invariably employed anæsthetics for the purpose.

2034. (*Lord Winmarleigh.*) From the first?—From the first. I feel perfectly satisfied that anything else would not be tolerated for a moment. No class of students, if I know anything about medical students, would tolerate the introduction of a living animal into the theatre, and a vivisection performed on that animal whilst the animal was not under the influence of some anæsthetic.

2035. (*Chairman.*) What you say with knowledge as regards Guy's Hospital, you say from general information and belief as regards the practice in this country generally?—I do. I do not mean to say that if only a few students were together when such experiments were practised, the same objection would always be raised by them as would be raised in the lecture theatre at Guy's, for instance, when a number of students were gathered together; for amongst a large number there would be sure to be found some who would object.

2036. And with regard to the general sentiment of physiologists and surgeons in this country, do you think you may venture to say, with regard to them, what you have said positively with regard to your own practice at Guy's?—I thoroughly believe so.

2037. Is it your opinion that the practice of experimenting on living animals has, in the last few years, been very considerably increased in this country?—I think not. There is a popular idea that it has been increased, which I think arises from this cause. A little time ago the College of Surgeons required a course of practical physiology; they wished the subject to be taught more practically than it had hitherto been, and required attendance on this course of practical physiology. I think that at the time the regulation was made, the authorities of the College of Surgeons scarcely understood what this course of practical physiology was to include; it was left to the lecturers. We tried to get information from them, but all we could hear from them was that they required that practical instruction should be given. This practical instruction now resolves itself essentially into practical histology, as I think my colleague, Dr. Pye-Smith, who superintends that course, will tell you, that is to say, work with the microscope, the microscopic examination of the tissues. The different organs and tissues are examined manipulatively; each student works with his own microscope; and my colleague superintends the course.

2038. (*To Dr. Pye-Smith.*) You are assistant-physician at Guy's Hospital and lecturer on physiology, together with Dr. Pavy?—I am.

F. W. Pav
M.D., F.R.
and P. H.
Pye-Smith
B.A., M.D

21 Oct. 187

2039. You have paid attention to the subject which has been referred to this Commission?—Yes.

2040. Are you of opinion that for purposes of medical discovery and science, it is possible to do altogether without experiments upon living animals, or that such experiments are necessary?—If by "medical study and science" you include physiology in the full sense, undoubtedly it is impossible that they can be done without.

2041. Are you acquainted with what is done in this country on that matter?—I believe I am.

2042. It is proposed as you know that we should report whether legislative interference of any kind is necessary for the satisfaction of the public mind, and for the prevention of the infliction of unnecessary suffering on animals. Are you prepared to offer any opinion to the Commission on that subject?—With regard to what may be necessary for quieting the public mind, I do not feel able to form an opinion. With regard to the other question, I should have thought that until abuses were proved, legislation was unnecessary. I am not aware of any necessity for it.

2043. You are not aware of any abuses?—No, I think I may say so certainly in this country.

2044. You are familiar with what is known, through published medical journals, of what is taking place in other countries?—Yes.

2045. Would you extend to all countries the opinion that there are no abuses for which correction would be desirable?—No, I do not feel able to do that.

2046. May I take it then as your general opinion, that it is not desirable that the practice in this country should become such as those journals would represent it to be in some other countries?—Yes, I think you may.

2047. And that if there were any tendency observable towards such a state of things in this country, it might modify your opinion as to whether any legislative interference was necessary?—Certainly.

2048. Reverting then to the practice in this country, is it your opinion, that a sense of humanity governs the physiologists and surgeons of this country in the practice to which they have recourse?—Yes, as far as my own experience goes, undoubtedly.

2049. In the first place, are anæsthetics used whenever it is possible to use anæsthetics?—I believe so. I always do so myself.

2050. Is the proportion of experiments in which anæsthetics can be used a very large proportion?—There is only a very small proportion of the experiments in which it is impossible to use anæsthetics.

2051. Then in the very large proportion of experiments, anæsthetics are used?—Certainly.

2052. And in those cases I suppose the anæsthesia is complete?—Certainly; it is badly done if it is not.

2053. So that in reality in those cases the animal is not subjected to anything that can be called torture?—I ought to explain perhaps that there is a certain set of experiments to which that would hardly apply; I refer to experiments in which it is desirable to ascertain the action of some drug, or the effect of some operation. The administration of the drug, or the performance of the operation, can take place under anæsthetics, and will cause no pain whatever, but the experiment is not then complete, and of course it is necessary that the animal should live after the recovery from anæsthesia for a certain time to see the effects of the experiments. During that time there may be a certain amount, not often I should think of pain, but of discomfort.

2054. Then we may take it generally that in the larger number of experiments complete anæsthesia is produced?—Certainly.

2055. Of the other experiments, in a considerable proportion the most painful part is done under anæsthesia?—Certainly.

2056. Then as to the small number of experiments that remain, are they very painful?—I confess I have very little experience in that. I have never performed an experiment on an animal, nor have I seen one performed, without anæsthetics.

2057. As a physiologist, is it your opinion that there is any large proportion which ought to be performed at all, and where the removal of pain by anæsthetics is impossible?—Certainly not.

2058. Is it within your knowledge that any incompetent persons perform experiments of this kind?—No, I have never known such an instance.

2059. Then you do not think that legislation is necessary for the purpose of preventing the practice falling into the hands of persons who ought not to be allowed to perform experiments?—I think not.

2060. (*To Dr. Pavy.*) Referring only to published medical reports with reference to what takes place in other countries, are you of opinion that there is nothing done in any other country which, if it were done in this country would be considered to call for legislative interference?—I think that more is done in other countries than is done here.

2061. More you believe to be done in other countries than would be allowed by the sentiment either of the medical profession or of the pupils in this country?—Yes.

2062. And which, if it were done in this country, would give the British public a right to consider whether legislative interference was not necessary?—Certainly. In support of what I mentioned just now, I should like to state that at the commencement of my course I am almost obliged to give a little apology for saying that the course will be an experimental one. I see upon the faces of the students sitting before me a feeling which leads me to consider it necessary to make some explanation, and to tell them at once that no experiment will be introduced which will wound the feelings of the most sensitive amongst them. I made use of that remark only a few lectures ago, and it is what I am constantly in the habit of doing, and I have found it necessary from what I have seen in my audience.

2063. With that feeling, I need scarcely ask you, both you and your professional brethren entirely sympathize?—Yes.

2064. Now are you at all aware or disposed to believe that the practice of experimenting on living animals falls sometimes into incompetent hands?—I have no knowledge of it at all.

2065. You do not believe it?—I do not believe it.

2066. You do not believe that that kind of suffering is inflicted upon animals in this country which would be inflicted if either bungling operators were to undertake it, or if the number of victims were increased by unnecessary and ill-considered experiments being performed?—I am not aware of anything of the kind. I do not know of experiments being undertaken by medical students.

2067. You do not believe that students in their private rooms do undertake experiments?—I do not believe it.

2068. If it should be established that such practices were introducing themselves into this country, would you think them worthy of legislative repression?—I think so, certainly.

2069. You have seen, I daresay, the various proposals that have been made for legislative repression?—Yes.

2070. Particularly two bills that were introduced into the two Houses of Parliament last session?—I took particular notice of the bill which was introduced by Dr. Playfair, and I felt that if that bill were introduced, it would alter nothing of what is done now.

2071. Meaning by that, if I rightly understand you, not that the bill would under all circumstances and in all countries have been inoperative, but that nothing in violation of it is now done in this country?—There is nothing, as far as my experience goes, in violation of it done in London.

2072. By the limitation "in London," do you mean that you are not acquainted so well with what goes on in other places, or that you purposely reserve the

F. W. Pavy, M.D., F.R.S., and P. H. Pye-Smith, B.A., M.D.

21 Oct. 1875.

remark exclusively to London ?—I reserve my remark to London, because my experience does not extend beyond London.

2073. You are not prepared therefore to give an opinion either way ?—No. I do not know what is done beyond London, but I do not believe that more is done in this country beyond London than is done in London.

2074. This at least may be said, that Dr. Playfair's bill would not be any restraint or impediment upon the legitimate practice of experimenting upon living animals, as you understand it ?—I consider that it would not.

2075. (*To Dr. Pye-Smith.*) You have heard Dr. Pavy's evidence; will you tell me whether you agree in it ?—Yes. And I may perhaps add one point on which I can supplement it. I know personally the gentlemen in charge of all the laboratories in England out of London; they are very few; namely, in Edinburgh, Manchester, and Cambridge, and I doubt if there is another. At Cambridge I worked myself, and I know what is done there, and it is exactly what is done in Dr. Pavy's laboratory. In Edinburgh and Manchester I have not been in the laboratories, but I know the officers personally, and from conversation and knowledge of their character, I am quite sure they would agree absolutely with what Dr. Pavy has said on this point.

2076. (*To Dr. Pavy.*) Have you any knowledge of what goes on in any private laboratories ?—I do not think there is anything going on in strictly private laboratories; I have no knowledge, I have not heard of it.

2077. (*Mr. Forster.*) Do you know of any private laboratories ?—I do not.

2078. (*Chairman to Dr. Pye-Smith.*) Do you know of any ?—No.

2079. (*Lord Winmarleigh to Dr. Pavy.*) I understand from your evidence, that you think that any legislative interference would be injudicious. You stated that you did not believe that there was any practical grievance connected with the subject of our inquiry that required legislative interference ?—It would pacify the public feeling if the bill of Dr. Playfair were passed; and I think that what the bill would enact would be nothing more than what is just. It would not alter my own course.

2080. You have of course either read or had some knowledge of the handbook for a physiological laboratory ?—Yes, I am quite familiar with it.

2081. To persons unacquainted with the details, there appear from that book to have been experiments made which must have given very great pain to animals, from the very description given of them ?—It is an unfortunate way of expressing it. The book has been written, and the experiments have been described just as though persons were to perform them, but that is not done.

2082. But I have got one experiment before me now where it appears to have been done ?—I mean not done in the schools.

2083. Then do you think that there are no other places where these experiments are made ?—Those experiments are principally described from continental sources. The persons who have written in that work have derived their information especially from continental sources.

2084. (*Sir J. B. Karslake.*) Do you think that there has been any tendency to increase the amount of vivisection in this country in consequence of the publication of that book ?—I think not.

2085. Although it points out how these things may be done, medical students and others are not in the habit, you think, of ascertaining whether they can do the things pointed out there ?—I do not think it is a book consulted generally by medical students; it is more a book for the advanced, for professors.

2086. I understand it to be your opinion, after considerable practical experience and knowledge on the subject, that medical students and others do not perform these operations and these vivisections in their own private rooms ?—Yes, certainly.

2087. And if there is any public opinion that that is the case, in your opinion that public opinion is ill founded ?—Unquestionably.

2088. How many courses of lectures do you deliver in the year ?—One course in the winter session of six months.

2089. What are the chief animals which you choose for the purposes of the experiments ?—Dogs, rabbits, guinea pigs; I suppose, if you are to include it amongst experiments, one might say also a dormouse, which is used just to show hibernation, but on which no vivisection is performed.

2090. I meant the animals on which vivisection is performed ?—Frogs, in addition to those already named; those are the chief animals.

2091. In every case are anæsthetics applied ?—For lecture purposes, except in the case of frogs, which are usually rendered insensible by pithing.

2092. So that no student sees an animal experimented on except under anæsthetics ?—No, not if there is a cutting operation performed upon it.

2093. In what cases do students see animals upon which anæthetics have not been used, and which are brought into the lecture room ?—I may give an illustration of what I have done already this year. To show the changing composition of the blood, I introduced into the stomach of an animal a liquid consisting of sugar and yellow prussiate of potash. This was effected by passing a flexible tube down through the mouth and the gullet into the stomach, and then it was injected by means of a syringe. No inconvenience at all was occasioned. The urine was afterwards collected by pressure over the bladder, and the rabbit, after this had been performed, was introduced before the students just to show what had been done.

2094. Was this rabbit afterwards killed or did it live ?—It lived; it had no pain or any inconvenience.

2095. It suffered no pain or inconvenience ?—No pain or inconvenience; the rabbit is alive and well now. It was not a cutting operation; no knife whatever was used.

2096. Can you give any notion of the number of animals that are used in the course of the series of lectures ?—I should think perhaps in the course of the session, say 20 dogs and 8 or 10 rabbits.

2097. And to those animals that you have mentioned the knife is actually applied ?—Under the influence of chloroform or some other anæsthetic, because we sometimes use puff-ball where we do not want to weaken the action of the heart.

2098. As far as your observation has gone, in every case has the anæsthesia been complete during the operation ?—Quite complete.

2099. There can be no doubt about that in your own judgment ?—No; and I would say further that the operation is very much facilitated by the anæsthetic being complete. If we had not anæsthetics to use we could not get on with our operative experiments as we now can. It is of the greatest assistance; apart from any question of humanity in the matter, the anæsthetic affords the greatest assistance to physiologists. The animal under anæsthesia lies perfectly quiet, and the experiment can be carried out without any interference whatever; whereas if the anæsthesia were not complete, the experiment in many instances would be interfered with.

2100. Do you find it at times necessary to repeat the administration of chloroform during the operation ?—We go on with the chloroform; the experiment may require that the animal should be kept under the influence of chloroform, for instance, for two or three hours.

2101. I think we heard from a witness that there are some particular regulations or rules as to the introduction of animals into the hospitals. Is that so to your knowledge ?—I am not aware of any.

2102. That there are certain persons who supply dogs and rabbits for vivisection, and there are rules

F. W. Pa
M.D., F.I
and P. I
Pye-Smi
B.A., M.

21 Oct. 18

issued by the authorities as to the mode in which these animals are to be introduced ?—No, not at Guy's.

2103. (*Lord Winmarleigh.*) How do you get them ?—The assistant gets them, he buys them; he goes over to Leadenhall Market and purchases our rabbits there and our dogs too.

2104. (*Mr. Forster.*) Without any concealment at all of the object ?—Certainly, they are brought in during the day.

2105. (*Chairman.*) I understand that you have nothing to conceal at all ?—Nothing at all.

2106. And desire no concealment ?—In the lecture room I may say that I have always lectured under the feeling that at any time a member of the Society for the Prevention of Cruelty to Animals might be present.

2107. I think we have been told by the secretary of that society that you offered to give them every facility of knowing everything that was done ?—I did, and said that they might attend the lectures when they liked. They visited the laboratories and had explained to them what was done.

2108. (*Mr. Huxley.*) I think I understood you to state that during the 20 years that you have been engaged in teaching physiology, you have always made use of these experiments as illustrations of your lectures ?—Yes.

2109. I judge from that, that you must very early have been convinced that the teaching of physiology without such practical illustrations is very maimed and imperfect ?—I felt so convinced of it when I came over from France, that I at once commenced to make the course an experimental course. I felt that instruction could not be perfect without it.

2110. I apprehend that you have gone through the ordinary training of a medical student, and you have doubtless paid great attention to chemistry ?—Yes.

2111. In going through that instruction, you must have gone through a course of practical chemistry, no doubt ?—Yes.

2112. And I presume that you must have derived the benefit from that study which everybody has done who studies chemistry, that is to say, you must be aware that your knowledge of chemistry is on a totally different footing when you have gone over the facts yourself from what it was before you knew them otherwise than by books ?—That is exactly what I have often said, that I considered that physiology could no more be taught without experimental illustrations than chemistry could.

2113. It is somewhat difficult to convey to persons who have not actually been engaged in the study of science, the intensity and the reality of the difference between knowing anything of your own knowledge because you have seen it, and knowing it from being told ?—When it is seen, it is so impressed upon the mind, that persons have a good foundation to work upon; without that foundation, they would often be at a loss just at the time when the knowledge was required.

2114. It has been replied to that argument that a surgical student is not allowed to operate on living bodies; but I take it that you would agree with me that the difference between a limb in a state of life and one in a state of death, so far as it is the subject of operation, is a difference of a totally different character from that which exists between a dead organ and a living organ in action ?—Yes.

2115. Whereas a man by studying anatomy may have a perfect conception of all the parts of a limb brought to him to operate upon, no amount of the study of anatomy can give him a notion of the action of the living parts ?—I agree in that.

2116. Then I should particularly like to have your opinion on one other point as a practical experimenter, and I ask the question without the slightest desire in any way to diminish the horror felt at the unnecessary infliction of pain, but rather with the desire of removing what is, to a certain extent, a prejudice. The question I put is this: Is it not within your experience that operations which, when described, sound exceedingly horrible, may, in reality, be performed with the infliction of what is really a small amount of pain. For example, I will take a particular case. It sounds a very horrible thing to say that a vessel of a live dog should be opened, and that a tube should be passed down it, and a certain quantity of blood taken therefrom; that sounds very horrible, but is it not a matter of fact that a dog will suffer that operation with less apparent manifestation of pain than he would exhibit if you pinched his tail pretty hard ?—Unquestionably, because the parts internally are not sensitive. And I would say further that I have frequently been unable to recognize the fact by the description. The description which has been given of an experiment has been so horrible, and likewise, I may say, so exaggerated, that I have not been able to associate the real fact with the description.

2117. There is another point which I should like to put to you. We have been told here that a vast number of what were called wanton and useless experiments are made by scientific investigators, experiments for no purpose, or no assignable purpose. Now you are familiar, I dare say, with scientific investigation, and the sort of pressure upon men's time which it involves. Are you aware that anything of that kind ever takes place ?—I am not.

2118. Do you think it likely that under the conditions of scientific life it should take place ?—I do not. Would you allow me to add that a great deal of the experimental part of our course consists of chemical and physical experiments. We illustrate the phenomena of life by chemical and physical experiments. A number of these experiments are introduced in relation to the circulation, respiration, and digestion; we imitate as far as we can the processes of life, and we consider that as belonging to the experimental part of the course.

2119. You are the author of a valuable work upon dietetics, I think ?—I have written a book upon dietetics.

2120. Have you been aided in the views you there express by your experiments upon animals ?—I think materially.

2121. (*To Dr. Pye-Smith.*) May I ask if you concur in the answers which Dr. Pavy has given to my questions ?—Yes.

2122. (*Mr. Forster to Dr. Pavy.*) You stated, in answer to Professor Huxley, that you agreed with him that the difference was very great in the advantage of teaching, which enabled a student to see an experiment from merely describing it to him. I, not knowing anything about medicine, should be much obliged to you if you could describe to me in what way there is a very great advantage to the medical student in his future profession from having had that kind of experimental teaching ?—The practice of medicine, one may say, is founded upon physiology. Unless we know the functions of the organs of the body in a state of health, we cannot be expected to realise what may be the condition in a state of disease. And I consider that by giving an experimental course, the knowledge of the functions of life is made more perfect than it otherwise could be.

2123. Could you illustrate that by any practical case which would show in what way a physician or a surgeon would be better able to practice the healing art by having seen an experiment ?—That may be taken generally and specially. I would say generally that our knowledge of disease must be based upon knowledge in a state of health. For instance, take the spinal cord; the symptoms which are produced by disease of the spinal cord are manifested at a distance from it. Now how can a person appreciate and give a proper interpretation to these symptoms which are manifested at a distance unless he knows what must be the functions of the spinal cord in a healthy state ? Before you can know anything of diseased

F. W. Pavy, M.D., F.R.S., and P. H. Pyé-Smith, B.A., M.D.

21 Oct. 1875.

action, you must be acquainted with what is healthy action.

2124. But would he not obtain that knowledge by walking the hospitals, and seeing the effect of the disease upon the spinal cord?—But supposing he did simply that, he would profit by the information which had been gained by physiology. The teaching is dependent upon the knowledge which has been acquired, and this knowledge has been acquired through experimental physiology.

2125. Can you give me a case in which a man could be called in by a patient, and in which from the fact that he has not had that knowledge, he would be less likely to do the patient good?—If he has simply got his knowledge from books or from lectures, the knowledge would not be impressed upon his mind in the same manner as if he got it from seeing the experiment performed. A man called in to treat a patient in the one case would have his knowledge at his command, in the other case it is possible the knowledge which he had acquired at lectures and likewise by reading would have vanished.

2126. Then, in fact, it comes to this, that you believe that in all cases the knowledge gained by sight is very much stronger than the knowledge gained by reading or by hearing?—I think the combination of the senses is needed. They hear, they read, and they see the experiment itself; and going through those channels, the information is much more likely to be indelibly impressed upon the mind.

2127. (*Lord Winmarleigh.*) May I ask you whether all the experiments that you have made at Guy's Hospital have had relation to benefits to be derived by the human frame from them?—I have always had that in view.

2128. Never performed such experiments simply from purely physiological objects?—It is physiology which is at the foundation of the treatment of disease.

2129. (*Mr. Forster.*) Do you lay this great stress upon the student's seeing the process upon this ground, that by seeing it, the knowledge that he gains by reading and hearing is very much deepened and confirmed, that is, the sensation upon him is much greater; or do you also think that he does, in seeing the experiments, get some information that he would not otherwise obtain by hearing and reading?—I do unquestionably. I think he is placed in an altered position. I think that by seeing an experiment performed, he is placed altogether in an altered position from what he would be in if he had not seen that experiment performed. He has got a foundation or substratum, as it were, which he could not otherwise have obtained.

2130. (*Mr. Huxley.*) Let me suggest another illustration of your view in the teaching of medicine. I presume that there is no teaching of medicine recognized unless there is a hospital attached?—No.

2131. That is to say, nobody would for an instant suppose that medicine could be taught to any useful purpose unless the student, not only had the opportunity of hearing disease described, but could go and see it in the hospital himself. That is a parallel case, is it not?—It is.

2132. (*Mr. Hutton.*) Of course you do not mean to deny that many good physiologists have been educated without this kind of education?—I should look upon them as physiologists occupying the same position as a physician who had not had practical experience.

2133. The argument is one of degree is it not? In point of fact your argument goes to this, does it not, That you ought to see some sort of experiment on living human beings in order to get still greater knowledge?—Certainly not.

2134. You would not deny, would you, that the knowledge would be larger which would be got by seeing the experiments on human beings?—I do not think it would.

2135. Surely the physiology is not the same of human beings and of animals?—There is no essential difference in fundamental points.

2136. The points at which the physiology of man branches off must be very numerous, must they not?—If you take the great functions, circulation, respiration, and digestion, those functions are carried on in the same way in the lower animals as they are in the human subject.

2137. And you think that no fresh instruction would be derived from seeing the same kind of experiments on men in any case?—Certainly that is my opinion; it would be quite superfluous, not at all required. As regards mental action there would be a difference certainly; but as regards the physical functions of life, they are performed in the same way in the lower animals as they are in the human subject.

2138. (*Mr. Huxley.*) That is to say, supposing we leave the phenomena of consciousness aside altogether, you could demonstrate all the truths laid down in a handbook of physiology upon a dog, could you not?—Quite so.

2139. (*Mr. Hutton*). The physiology of the brain is not the same, is it, in the dog and the human being?—As regards the elementary functions it is; the higher functions are different.

2140. Did the description which you gave just now of your experiments apply simply to the lecture room or to the laboratory also?—I perform two sets of experiments, those which are directed towards instruction, and those which are directed towards research.

2141. Did what you said just now refer to the experiments directed towards research?—The experiments directed towards instruction are invariably performed, whenever there is any cutting operation concerned, under the influence of an anæsthetic, and the experiments directed towards research are also almost invariably performed under the same state. I will not say that there may not have been an exception, because in some instances I have thought that the chloroform may have interfered with the conditions to be observed, and in order to see whether that has been the case or not, the experiment has been performed without the chloroform.

2142. But it is usually employed in your laboratory as much almost as in the lecture room, is it?—We never think of experimenting upon an animal without the chloroform; it must be something very special indeed to lead us to do so.

2143. Have you ever made experiments on the effect of strychnine on animals?—Yes.

2144. And you have proved, have you not, that death under strychnine generally takes place from the ceasing of respiration?—It does.

2145. In that case were you able to use chloroform?—Yes.

2146. The chloroform did not in that case interfere with the success of the experiment?—No. There is an experiment which I perform at lecture in which the animal is placed under the influence of chloroform, and some strychnine is introduced into the circulation whilst the animal is under the influence of the chloroform; and whilst the animal is still under the influence of the chloroform it dies immediately.

2147. But if you keep up artificial respiration it does not die?—But that is not done.

2148. But you have done such experiments yourself in the laboratory?—Yes, I think I have. I was performing some experiments some years ago upon woorali and strychnine.

2149. And under those circumstances the animal would suffer, would it not, because you could not keep up the anæsthesia?—I think the animal under the influence of the poison would not be in a position to feel pain in the same way as if the poison had not been used.

2150. You said that that handbook of physiology which has been referred to was used for accomplished physiologists. Now the very first line I read in it, "This book is intended for beginners in physiological work." Does not that imply that the editors

F. W. Pa
M.D., F.
and P.
Pye-Smi
B.A., M.

21 Oct. 18

did not take the same view as you take of it?—Unquestionably; but I do not believe that the book is used by any beginners; I do not see how it can be used by beginners.

2151. It was supposed by the editors that it would be used by beginners?—But persons are not always right in their suppositions.

2152. You say, as I understand you, that the classes of experiments recommended in that book are almost always painless. Will you kindly look at that contained at page 403, on recurrent sensibility, and on that at page 409, where the frog is gradually raised to 30 or 40 degrees centigrade in water; must not both of those experiments be very painful?—I did not say that they were painless experiments. The first of those experiments, to begin with, is performed under the influence of chloroform.

2153. But you will see that the roots are stimulated, and that the experiment depends upon the pain in the after part of it?—Yes; but all I can say is that that experiment would not be performed at Guy's.

2154. But still the effect of that handbook would be to suggest to a physiological lecturer that such an experiment ought to be performed?—But I am not responsible for the suggestions which are made in that handbook.

2155. But I understood you to say that you did not believe the method of vivisectional experiments to be extending in this country, or to be likely to extend. Surely this is a symptom that it is extending, and likely to extend?—Nor do I think that it is being extended by this book which has been written.

2156. Do you not suppose that all those experiments had been tried by Dr. Burdon Sanderson or the other editors of that book before they published it, and that they usually practice them in their laboratories?—Very likely the majority have been tried, but I should say not all; and, as I mentioned just now, the greater portion of the evidence given in that book is from continental sources.

2157. (*Chairman.*) The experiment to which your attention has been particularly directed is one which you would not think it proper to introduce at Guy's?—I feel sure that the students would not tolerate it.

2158. (*Mr. Hutton.*) Do you mean that you would not introduce either the one or the other. Those two are only specimens of a very large number of experiments, and I wanted to know whether you thought that the effect of that handbook would not be to recommend such experiments to our English lecturers. One of these experiments is on two frogs; a healthy frog which makes an effort to escape; and another frog which, as I suppose, is pithed?—Yes, it is pithed.

2159. But I suppose the healthy frog suffers very much the experience of being put into boiling water?—I should think not. The temperature is gradually raised, and before the frog could experience the effect which would be experienced by being put into boiling water, the sensibility would become altogether destroyed.

2160. I suppose the frog would feel very much what we should feel if we were to be put into water and the temperature gradually raised to the boiling point?—I think we should not feel any pain. I think that when the temperature got to 110° or 112° the condition of the body would be so altered that pain would not be experienced. I should explain that there is a difference between being in water at 110° and in the atmosphere at 110°. The water would have the effect of raising the temperature of the body, and when the temperature of the body reaches about 10 to 12 degrees above the normal point death ensues; so that death would ensue long before the animal could be subjected to the influence of the boiling water.

2161. (*Mr. Forster.*) Would it not be the case that either you or I would suffer very much more pain if we were suddenly to put our bodies into boiling water than we should if we put them into cold water, and then the temperature was gradually raised?—I do not think that in the latter case pain would be experienced; death would be produced by the destruction of the vital capacity of the tissues long before the boiling point was attained.

2162. (*Mr. Hutton.*) The evidence is that the frog made great efforts to escape; which I suppose means that the frog suffered a good deal?—I do not know that you must interpret it in that way. There may be a physical action on the muscles causing those efforts.

2163. All I wish to obtain from you is that you do not think the experiments in this handbook are experiments which you would think it desirable should be adopted in the physiological schools of this country?—Certainly, I would say so.

2164. (*Lord Winmarleigh.*) Have you gone through the whole book?—The greater portion of it; but taking the book altogether, I think there are a great many experiments in it not adapted for repeating.

2165. (*Mr. Huxley.*) You mean by that not adapted for physiological laboratories meant for teaching ordinary medical students?—Yes.

2166. But if they were physiological laboratories for the education of physiological students proper, would you see any objection to the experiments?—They should be prepared with due care and caution.

2167. (*Mr. Hutton.*) But even the most painful of those experiments, those purely demonstrative, you would think would be right for the purely physiological laboratories, would you?—Where a person was prosecuting physiology so that he might make some advance which might be of benefit to mankind, I should consider that he would be justified in resorting to measures which would not be justifiable in the case of ordinary students.

2168. But as to both of those experiments to which I have been calling your attention, they are not experiments essential for research, but experiments desirable for the purpose of teaching students in the one case the action of the nerves in relation to what is called recurrent sensibility, and in the other case the reflex-action of the frog's nerves; they are not experiments in the course of new research, but experiments for the purposes of teaching?—Yes; but because they are recommended in that handbook it does not follow that we should repeat them.

2169. I only want to get your repudiation of them as experiments for the purpose of teaching?—I should not consider myself bound to do anything but what I considered conscientiously right.

2170. (*To Dr. Pye-Smith.*) Do you agree with Dr. Pavy's answers on this subject?—Yes, as far as I follow your questions.

2171. Do you think that for the purposes of teaching, these painful experiments are desirable, even with a class of advanced physiologists?—I should say that is a question which must be left to the judgment and the conscience of each teacher.

2172. In fact you would not disallow them?—I would not disallow them by law so long as I had confidence in the teacher.

2173. (*Chairman.*) But we have understood from you that in other countries things do go on which you do not approve?—I have reason to believe so.

2174. And you have reason to believe that this handbook before us is borrowed chiefly from continental sources?—Yes.

2175. And you do not associate your reputation with these experiments which are recommended in this handbook, but on the contrary you withhold that association very clearly, on the ground that they are not suited, at least for the purposes of Guy's?—I should draw a very great distinction between the amount of physiology which it is necessary to teach those who intend to practise medicine, and the amount which it is necessary to teach those who are themselves to teach and to carry on the study of physiology. This handbook is intended for both, but much more for the latter class, and for the latter class, while I would not bind myself to every individual sentence there, I confess that I think there is nothing there that is not perfectly justifiable for that purpose.

2176. You say that you would trust the conscience

F. W. Pavy, M.D., F.R.S., and P. H. Pye-Smith, B.A., M.D.

21 Oct. 1875.

of the person who is to perform the experiment, but suppose there are persons whose consciences are not trustworthy, would you think it unreasonable that there should be some security that improper things of this sort were not done?—I would venture to suggest that that is a question for experience. Where any wrong or abuse is shown, I think every physiologist would wish that it should be stopped, if necessary, by law, where public opinion among physiologists is not sufficient, which it is at present. I know personally each of the gentlemen who wrote this book, and I should feel at least as much confidence in their judgment and their humanity as I should in my own.

2177. (*Lord Winmarleigh to Dr. Pavy.*) You said that there are some cases in which it is impossible to make these experiments under chloroform, but I think you said they were few?—Very few indeed.

2178. Would it be possible to draw a distinct line between the cases in which chloroform cannot be used and those in which it can be used?—That must be left to the physiologists; there can be no distinct line drawn, I think.

2179. Supposing, for instance, it was proposed to legitimatise experiments under chloroform, there is no possibility of making an exception as to certain cases which cannot be performed under chloroform?—I consider that no line can be drawn, simply because you cannot foresee the kind of experiments which are likely to be required. As knowledge advances we experiment in a new line, and you cannot foresee what line of experiment might be required; so that by legislation I do not understand that any hard line could be drawn.

2180. Speaking of what has prevailed up to the present time, what are the particular cases in which you cannot use chloroform or anæsthetics, and which you allow to inflict considerable pain upon the animal operated upon?—There are none at the present time, but I was referring to what I had done, for instance, in experiments relating to the blood. I had reason to think that chloroform might have interfered with the experimental result which I obtained, and I felt it necessary to perform the experiment in the absence of chloroform, so as to see whether the experiment had been vitiated by the chloroform or not.

2181. But I think you stated that that could be done without pain to the animal?—Chloroform may be administered first, and the cutting operation performed, and the animal allowed to come round from the influence of the chloroform, and the blood subsequently collected and examined.

2182. Can all the experiments with reference to the liver and so on, all without exception, be performed under anæsthetics?—I do not remember one that cannot at the present time.

2183. Can the experiments relating to the nerves connected with the brain, and so on?—With regard to the nerves, with some of those experiments it would be necessary that the animal should not be under the influence of chloroform.

2184. And would those be very painful?—I do not consider that any material amount of pain need be inflicted, because all that would be required would be to just see the result, and then no unnecessary prolongation of suffering need be produced.

2185. (*Chairman.*) I understood you to say that a bill framed generally upon the basis of Dr. Playfair's bill would not be restrictive of anything which is now done by physiologists in this country?—I felt, on looking through that bill, that it would not restrict the course which I was myself pursuing.

2186. (*To Dr. Pye-Smith.*) Is that your opinion also?—Yes. I think it might possibly to some extent throw difficulties in the way, but not seriously. But it would, I think, throw a kind of stigma over physiological experiments.

2187. Then it is merely a sentiment, that it would involve what you consider to be an undeserved stigma upon the profession in this country?—Yes.

2188. But it would not you think, interfere with anything which those whom you are acquainted with, or whom you believe to be the principal physiologists in this country, really practice?—No.

2189. It would therefore be operative, if at all, against other persons outside those whom you have in your contemplation?—Yes.

2190. Then if it should so happen that there was sufficient reason to think that there either are now or may hereafter be persons of a different description from those whom you are acquainted with, you would not see any very serious difficulty in the operation of the bill?—Certainly not.

2191. (*Mr. Forster to Dr. Pavy.*) I understand by your answers, that you would see no objection to the prevention of all experiments for merely demonstrative or teaching purposes in which anæsthetics are not used?—Anæsthetics used at the commencement or during the operative part of the experiment.

2192. Anæsthetics used in the same manner as they are in your experiments at Guy's Hospital?—Yes.

2193. (*Mr. Erichsen.*) You said that the experiment on recurrent sensibility would not be tolerated by the students at Guy's Hospital?—Yes.

2194. I suppose we may take it that you mean that the students at Guy's Hospital are a fair average sample of the students at all well conducted schools of medicine in this country?—I think so.

2195. And if a large body of gentlemen like the students at Guy's Hospital would not tolerate that experiment, it is also to be supposed that large bodies of students in other schools would have the same repugnance to it which would be manifested at your school?—I think so.

2196. And consequently that in all probability no teacher of physiology would demonstrate such an experiment as that to his class?—Not to his class.

2197. You have been in the habit of demonstrating more largely I think than most teachers of physiology, for a longer period, at all events for the last 20 years, before very large classes, and having been a teacher for so lengthened a period as that, you must have had an opportunity of seeing and judging of the progress of the men that you have taught in after life?—Yes.

2198. Have you found that the practice of attending demonstrations of physiological experiments or in physiological laboratories where experiments are made, tends to harden the heart or to alter the character injuriously of those who study in that way?—I do not think so.

2199. You do not think so from your experience during that lengthened period, and having been able to trace the progress of these men after their establishment in practice?—I think certainly not.

2200. Besides those experiments which are demonstrative experiments which you have been in the habit of performing, there are a series of observations which may be submitted with great advantage to students, I presume, in your opinion, which are not exactly experiments, but by which certain actions going on in the living body are visible and can be shown; such, for instance, as the action of the heart in an animal which is pithed, but in which artificial respiration keeps up that action?—Yes.

2201. Now do you think it could be possible for anybody who has not seen the contractions of the heart and of the different chambers of the heart under those circumstances to form a correct estimate really of the action of a living heart?—I think not. As I mentioned in answer to a question previously, I think that a person who has seen these things is placed in a different position from a person who has not seen them.

2202. And that the physician who has seen such a thing as that would be better capable in his practice of judging of the morbid action of a living heart, from the fact of his having seen the healthy action in a living animal?—I consider unquestionably so.

2203. Then again with regard to such an observation, which may be made in the same way, of the

F. W. Pavy, M.D., F.R.S., and P. H. Pye-Smith, B.A., M.D.

21 Oct. 1875.

peristaltic action of the intestines, in examining that, do you think that a surgeon who has seen that movement would be able to form a better conception of such a disease as intus-susception than a man who has never seen it?—I think that seeing the peristaltic action of the intestines gives an idea which would be of incalculable service to a surgeon after.

2204. (*Lord Winmarleigh.*) He would not derive the same knowledge from theory, you think?—I do not see how he can have a correct conception without seeing it.

2205. You have never found any practical difficulty in keeping animals under anæsthesia sufficiently long for all purposes of demonstration as well as of experiments out of the class room?—Not the slightest. An animal may be easily kept under the influence of chloroform for three hours. I have done this myself within the last two months.

The witnesses withdrew.

Adjourned to Saturday next at 2 o'clock.

Saturday, 23rd October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

Mr. J. BURDON-SANDERSON, M.D., F.R.S., and Mr. MICHAEL FOSTER, M.D., F.R.S., called in and examined.

Mr. J. Burdon-Sanderson, M.D., F.R.S., and Mr. M. Foster, M.D., F.R.S.

23 Oct. 1875.

2206. (*Chairman to Dr. Burdon-Sanderson.*) You are Professor of Human Physiology in University College, London?—Yes.

2207. But you represent the London University in your professional capacity, do you not?—I am the Superintendent of the Brown Institution, which is immediately under the London University.

2208. (*To Dr. Foster.*) You are Prælector of Physiology in Trinity College, Cambridge?—Yes.

2209. (*To Dr. Burdon-Sanderson.*) You are the author of one part of the "Handbook for the Physiological Laboratory?"—I am.

2210. (*To Dr. Foster.*) And you are the author of another part?—Yes.

2211. (*To Dr. Burdon-Sanderson.*) We were told the other day that this book had been very much founded upon experiments conducted in foreign countries; is that so?—The whole subject of physiology is founded to the extent of about perhaps nine parts out of ten upon experiments conducted in foreign countries, because physiology has been very much neglected in England during the past 20 years.

2212. Then you consider, do you, that physiology is now taking what may be considered rather a new start in England?—I hardly think that. It is to a certain extent taking a new start, but it has not yet taken any very decidedly new start. The science has progressed very considerably, as I have already said, in all countries during the last 25 years; and all that has been done lately is to organize schools of physiology in a more complete manner than they were organized before.

2213. In this country you mean?—In this country.

2214. This book is prepared with a view to a more general study of physiology in this country than we have had heretofore, is that so?—I should rather answer that question thus: it has been prepared for the purpose of enabling those who are engaged in the experimental study of physiology to do it in the most effectual way.

2215. In short, to give what I said before, a new start to a science which you said has hitherto been very much neglected in this country?—Exactly.

2216. You are acquainted with the practice of the foreign schools upon this subject, so far at least as it may be known from the published medical journals?—I am.

2217. We have understood from many very eminent witnesses who have been before us, that there are many things done on the continent in regard to this subject which would not be approved if they were introduced here either by the medical teachers or by the medical pupils, is that your opinion?—It is rather a dangerous question to answer. Investigations in physiology are conducted abroad by men of very great eminence; at no previous period in the history of the science have so many great men lived as at the present moment; and to speak of such men in terms of criticism would be perhaps rather bold, but there are certainly things done in connection with teaching abroad, and even in connection with research, which ought not to be done on humanitarian grounds, if I may be excused for using the word.

2218. If therefore the Legislature and the British public should think it desirable to prevent the possible introduction of similar practices into this country, you would not be prepared to dissent from that desire on their part?—It would depend entirely upon the way in which it was done.

2219. I am assuming that it was done in a reasonable and sensible manner; but I am now speaking of the object to be attained, you would not dissent from the object which the Legislature in the supposed case would have in view?—Certainly not.

2220. I think you were acquainted with Dr. Playfair's bill at the time that he introduced it into the House of Commons?—I was, and took an active part in regard to it. I had some conferences with Dr. Playfair on the subject, and with other gentlemen; and in the main I approved of it, and thought it was a suitable measure.

2221. Now in the general sentiment which has been expressed here by so many of the most eminent medical men, that the giving pain to animals is a great evil, and should, as far as possible, be avoided, I am sure I may take you as entirely agreeing?—Entirely.

2222. So that if an experiment could be tried with complete anæsthesia, and complete anæsthesia were not employed, you would condemn it very much?—I should condemn the non-employment of anæsthesia.

2223. If an experiment was in your opinion absolutely necessary for the attaining of some point of physiological knowledge, and it was a painful experiment, an unnecessary repetition of that would be equally foreign to any approval of yours, I presume?—I should be very cautious in finding fault with anybody for repeating an experiment; because all facts in science require repeating in order to make them certain; and of course it is extremely difficult to judge how often an observation must be repeated. It must be repeated a sufficient number of times for us to be sure that no error exists, because if a fact goes forth which

Mr. J. Burdon-Sanderson, M.D., F.R.S., and Mr. M. Foster, M.D., F.R.S.

23 Oct. 1875.

has not been made sufficiently sure by exactness of observation, without referring to the scientific evils which would arise therefrom, it would lead to the making of additional experiments for the purpose of making it certain.

2224. That you consider is frequently a very difficult point to determine ?—A very difficult point.

2225. One which ought to be determined, if at all, by the most competent and most scientific persons ?—I am strongly of that opinion.

2226. And ought therefore not to be left to the judgment of every person who might imagine himself to be a competent person, when perhaps nobody else would be likely to be of the same opinion ?—No doubt.

2227. As far as your knowledge and information go, the practice in this country is different from that of which we have spoken as known to prevail in some other countries, is it not ?—The sentiment is quite different among physiological workers, and consequently the practice is different.

2228. The sentiment in this country has been thus in your opinion quite correctly described to us as being a sentiment that pain is a great evil, that it should be avoided where possible, and, where it is not possible to avoid it, should be minimized ?—Certainly.

2229. And that the utmost care should be taken to accomplish that in every experiment that is tried ?—Certainly.

2230. We were told by the teachers of one of the most eminent schools in London, that in all demonstrations at their school complete anæsthesia is resorted to. Is it your belief that that is the case generally in all the schools in this country ?—I can only say what my own practice is. I always have been in the habit at the beginning of my course, long before this present agitation commenced, of explaining to students that in all experiments which were used for demonstrational purposes, the animals are anæsthetised.

2231. So that an entire absence of pain may be predicated so far as demonstration to pupils is concerned ?—Certainly, in my school it is so. There is one observation I should like to make, namely, that outside of the ordinary teaching of physiology comes a subject which belongs to physiology, but would not be ordinarily included in it, namely, the subject of pharmacology, including toxicology. In this case if anything is to be shown to students (and I think it is most desirable that the actions of some of the most important poisons should be shown), the experiments would necessarily be attended with pain. It does not come within my scope to make such experiments before students, or to show them ; but I should not think that a teacher of pharmacology was not justified in exhibiting the effects of some of the most important poisons, although that might be attended with pain.

2232. And although the action of the poison was perfectly well known, and therefore no new scientific information would be obtained by that particular experiment ?—I mean that. I refer to certain poisons of which the action is extremely characteristic, which kill the animal used, but cannot be said to kill the animal without pain ; you cannot call it a case of euthanasia ; it is a case in which death does not take place in so short a way as it might be produced ; but it does not strictly come within the definition given of experiments made to illustrate the subject of physiology.

2233. Would that remark apply to cases such as have been mentioned here, of animals having been starved to death, or nearly to death, in order to show pupils that a very small injury will terminate life in an animal so reduced ?—As to such an experiment as that it would be of course very objectionable to make it for demonstrational purposes, and it would be altogether uninstructive. I was alluding for example to such a poison as strychnia, as to the action of which no one can form a vivid conception unless he has seen an animal under its influence.

2234. The point which I want to have as clearly as we can get it on the notes is, whether the experiments in toxicology, which you think ought not be excluded from experiments of mere demonstration to pupils, are of a very severe and protracted nature, or whether they are of a less severe and protracted nature ?—They are all of them very short indeed as regards the time during which the suffering is inflicted.

2235. So that what you contemplate as regards the demonstration to pupils is, as regards the use of the knife, a complete absence of pain ?—Yes.

2236. And as regards the use of poisons, only a comparatively slight suffering of pain ?—Yes.

2237. And in very rare cases ?—In very rare cases. There again I refer to the purpose of teaching.

2238. I am asking you now with regard to poisons entirely in regard to demonstration to pupils ?—Yes, I understand the question in that way.

2239. Now in the book to which we have already referred, I observe in the preface that it is said to be a book "intended for beginners ;" but I do not understand that you mean that pupils, or any but advanced students, are to practice any of these experiments ?—The book is intended as a guide for persons who are engaging in scientific investigation. It is not intended at all for students in the ordinary sense of the word, as meaning students of medicine. It is intended for students of physiology, and not for students of medicine. I may illustrate that by saying that at the beginning of each of my courses of physiology, when, as is usually the case, one points out to students the books that they ought to purchase, I always tell them, "You know the handbook for the physiological laboratory, but that is not a book that I recommend "you to buy, because that is not intended for the ordinary student to provide himself with; that was "written for the purpose of helping persons who are "engaged in physiological study, and want to make "either physiological, pharmacological, or toxicological "investigations, requiring a knowledge of what has "been done before, and the way in which it has "been done."

2240. So that to interpret the words "intended for beginners" as meaning that anybody who goes as a medical student to one of the great hospitals is to read this handbook, and apply it for himself, would be entirely to misapprehend what I understand you to say is your meaning ?—Entirely, it means beginners in research. It would be correct if you were to introduce the two words which I have now given after the word "beginners," namely, "in research."

2241. The word "beginners" then means, as I gather, people who have already attained very considerable surgical skill ?—Not surgical skill, because surgery has no necessary relation to physiology, but considerable knowledge in physiology.

2242. By surgical skill I mean that if they are to apply the methods suggested in this book, they should be people competent to apply them with the utmost skill that anybody could be expected to possess in such an occupation ?—Quite so. And I think this gives me an opportunity of saying that the state of things which we should like to see established with reference to physiological research is such as would unquestionably discourage the making of experiments by anyone, excepting by persons trained in what I should call a school of physiology ; and by a school of physiology I do not mean a system of lectures, but a place where research is carried on under the supervision of skilled persons, such persons being assisted by persons less skilled, who would in that way of course have the opportunity of acquiring the skill of which you speak.

2243. I want for the present to ascertain whether any precautions which may be indicated in the book for the purpose of either preventing or diminishing suffering would be in the hands of beginners, who might be bunglers, or would be in the hands of persons whose previous teaching had made them competent to use such precautions with the greatest proficiency ?—It is our intention that the experiments referred to in the book should only be made by com-

Mr. J. Burdon-Sanderson, M.D., F.R.S., and Mr. M. Foster, M.D., F.R.S.

23 Oct. 1875.

petent persons, and that the accounts of them should be used to assist persons who are competent, and who have made themselves competent in the best possible way, to make experiments.

2244. Now I should like to ask you a few questions about some of the experiments in the book, in order that you may illustrate more fully what you have already said. Now I have before me the experiment on page 235, No. 47, that is called "Experiments "relating to the influence of the cerebro-spinal "nervous centres of the vascular system," and the first heading is "Destruction of the nervous centres"; and it begins—"Two frogs are slightly curarised." Is curari an anæsthetic?—The action of curari is now under investigation. It is a very complicated question indeed to enter upon, and it would take a long time to discuss. There is every reason to believe, as regards the frog, and the animals belonging to that group, that we have got pretty exact knowledge with reference to it. As regards the higher animals we have always treated it as if it were not an anæsthetic; that is to say, we have always considered it necessary (in experiments of research I am talking about now) when any painful operation had to be done, to use anæsthetics with a view to such painful operation.

2245. And in that case you would not consider curari an anæsthetic?—Certainly not, so far as regards the higher animals, so far as we know. I mean we act as if we did not consider it so.

2246. Do you draw a distinction between the frog and the higher animals, and hold that curari is an anæsthetic in regard to the frog?—So far as the thing has been investigated, everything tends to show that it is.

2247. Are you acquainted with the recorded opinion of Claude Bernard upon the subject of whether curari is an anæsthetic or not?—Claude Bernard was the first who investigated the subject of curari.

2248. And we have been given to understand that it is on record as his decision on the subject, that curari is not an anæsthetic; and I had not heard before that there is a distinction between the frog and the higher animals in this respect. Do you hold that it is established that there is that distinction?—It is not at all established that there is a distinction in that matter between the frog and the higher animals, because we do not know the action of curari on the higher animals, but we do know it in a great measure with reference to the frog.

2249. But we have been given to understand by some of the evidence before us that curari operates upon the motor nerves and does not operate upon the nerves of sensation. Do you hold that to be the right opinion?—There is a very marked difference between the action of curari on the motor and the sensory nerves.

2250. So that on the sensory nerves it is not at any rate ascertained that it operates so as to produce anæsthesia?—With reference to the frog we have not the slightest evidence that the frog feels any pain under the influence of curari.

2251. But I understand you to say with regard to the higher animals that you have so little faith in curari that you always think it necessary to use some other anæsthetic?—We do so. I am speaking of my own practice, what I should do myself, and what I have done.

2252. But I am speaking of this handbook which is intended, not for your own practice, but for the guidance of those who are to profit by it, and I have adverted to this particular experiment which I presume I may take to be a very painful experiment if it were performed without any anæsthetic?—I think with regard to the frog, that a frog under the influence of curari is to the best of our knowledge in a condition in which the consciousness of pain is extremely small, that is all I can say about it.

2253. But this is in its nature, is it not, a painful experiment, supposing there to be no anæsthetic used?—It cannot be a very painful experiment because the injury done is relatively slight. This is a case in which the heart of a frog is exposed, and that is the only operation that is performed in that particular case.

2254. Take the next one, No. 48, at page 237. "All "being now ready the integument is opened along the "middle line of the back of the neck and the occipital "bone perforated in the middle line with a fine awl, "close to its posterior margin. The frog is then "laid, back downwards, on the board, in such a posi"tion that one of the needles enters the cranium "through the hole in the occipital bone, the other "the spinal canal. The web is then laid on a plate "of glass, which covers the notch, and secured if "necessary by fine pins. Finally the heart is exposed "as before," and so on. Now when you speak of a painful experiment would you include that in the category of painful experiments?—The source of pain, if anything, would be the introduction of the pins which are mentioned here, because those pass through the integument of the frog; but of course I need not say that the amount of pain produced would be extremely small.

2255. In the whole experiment do you mean?—Extremely small, supposing the animal were not curarised I mean.

2256. Then whatever the pain may be in such an experiment as that you think curari is a sufficient anæsthetic to employ?—Certainly, it would be most absurd to use any other, absolutely absurd (I can speak of that afterwards), bearing in mind that these are experiments of research.

2257. (*Lord Winmarleigh.*) With a particular object?—With a particular object.

2258. (*Chairman.*) I am now speaking entirely of whether it is very painful, and whether curari is an anæsthetic, not with respect to the importance of the object; and I understand you to say with regard to that experiment that it is not very painful, and that curari is so sufficient an anæsthetic, that it would be absurd to employ any other?—I used that expression "absurd to employ any other" because any other anæsthetic which you could employ would not be beneficial to the animal itself, even looking at it in that point of view.

2259. Now on page 269, Experiment No. 74, is this: "A frog having been slightly curarised or "rendered motionless by section of the medulla, is "fixed in the prone position. The sternum is then "divided in the middle line, and the two halves of "the wall of the cesht drawn to either side, so as to "expose the pericardium and lungs, while a stout "glass rod is passed down the æsophagus." Do you consider that a painful experiment?—I may remark with reference to this experiment, that if the experiment is properly done, it is one which can be done without pain at all; because it is one which can be done after the destruction of the brain. I am sorry to see that that is not so distinctly stated in the book as it might have been.

2260. Supposing the brain to have been destroyed, would it then be necessary to curarise the frog for this purpose?—Not necessarily to show the facts which are referred to there.

2261. So that it is rather an oversight to say that the frog may be "slightly curarised;" it should have been said that the sensation of the frog should have been destroyed?—I think so.

2262. Now on page 278 I find this: "In a "curarised rabbit, in which artificial respiration is "maintained in the usual way, an incision is made in "the middle line, extending from the upper third of "the sternum to the upper end of the trachea. The "external jugular vein of one side is then brought "into view, tied in two places, and divided between "the ligatures," and so on. Now is that in its nature a painful experiment?—There is no doubt that it is a painful experiment.

2263. Now you seemed to suggest to us a little while ago that a frog differed from what we call the higher animals in respect of the operation of curari. How does a rabbit stand in regard to the operation of

Mr.
J. Burdon-Sanderson,
M.D., F.R.S.,
and Mr.
M. Foster,
M.D., F.R.S.

23 Oct. 1875.

curari ?—The observation that I made just now applies to it ; we do not know what the action of curari on the higher animals is at all as regards the relation between sensibility and voluntary motion ; but we treat the case as if curari did not make the animal insensible. For all such operations as these, of which you have read the description, one would use another anæsthetic ; and we have at hand an anæsthetic for that purpose, namely, chloral in the case of a rabbit.

2264. (*Lord Winmarleigh.*) Not in the case of a frog ?—Not in the case of a frog.

2265. (*Chairman.*) It says here "in a curarised rabbit." Do I rightly understand that that ought to be "in an anæsthetised or narcotised rabbit"?—May I make a general observation in reference to this book, namely, that we had not in view the criticisms of people who did not belong to our craft in writing it, and that we did not guard against all possible misunderstandings of that sort. It is generally understood that we use anæsthetics whenever we possibly can, and consequently that is a thing taken for granted. That ought to have been stated much more distinctly at the beginning in a general way ; but it was not stated for the reason I have given.

2266. Then I may assume that in any future communications with the "beginners," for whom the book is intended, greater pains will be taken to make them distinctly understand how animals may be saved from suffering than have been taken in this book ?—Yes ; I am quite willing to say that.

2267. Sir John Karslake suggests to me this question : In the case of a rabbit, would not it have done quite well to say "in an anæsthetised or narcotised rabbit," or whatever the proper phrase is, instead of "a curarised rabbit"?—It would not have done, because the object in this particular experiment was to cut off one set of functions, namely, the functions of voluntary motion ; that was absolutely necessary for the purpose of the experiment. You cannot possibly make any experiment bearing upon the condition of pressure in the circulation in which you have the interference of muscular action, for instance, the rhythmical motions of respiration, inasmuch as each muscular act of respiration modifies the mechanism of circulation.

2268. I understand you that the special action of curari is to prohibit the action of the motor nerves ?—Yes ; the purpose being to simplify the conditions of the experiment by shutting off the greatest function, namely, the function of the muscular system.

2269. Then for this experiment it is essential that curari should be used ?—I must just refer to the precise nature of the experiment to point out why. This is one of the experiments in which curari must be used for the reason I have stated, namely, that the whole thing depends upon the conditions of circulation, and that the conditions of circulation are modified by the presence of muscular motions of any kind, and particularly those of respiration.

2270. Then for this experiment it is essential to use curari ?—It is essential to use curari, whether you use another anæsthetic or not.

2271. Then if it were properly explained to those who are to use the book, it would be understood that besides an anæsthetic, which would completely destroy the sense of pain, curari should be given to destroy the action of the motor nerves ?—Precisely.

2272. So that what is wanted is that the pupil should be told that the animal here is to be anæsthetised ; and you think that it was the intention of the book that that should be understood by everybody ?—By everybody doing any such experiments, certainly.

2273. Though I think you now see that it would be desirable that that explanation should be made a little more clearly in future ?—Yes.

2274. Now on page 308, at No. 101, I find this : "Death after section of both vagi. Rabbits in which "both vagi have been divided commonly die before "the end of the first day. Dogs live longer ; often "two or three days." Now is the section of the vagi a painful experiment ?—Yes.

2275. (*Lord Winmarleigh.*) What are the vagi ?—The vagi are two nerves which supply the organs of respiration and those of disgestion, and in fact preside over the most important functions of the internal organs.

2276. (*Chairman.*) Then, that experiment No. 101 is a painful experiment ?—It is a painful experiment, and one which would not be done excepting purely for the purpose of research.

2277. Then after the animal has been anæsthetised for the purpose of performing the section, there still remains to rabbits a portion of a day, and to dogs a much longer portion, often two or three days of a very painful state of existence ?—Yes. But may I draw attention to the fact that no one is recommended to do this experiment ; it is not mentioned as an experiment to be done by anybody. The paragraph is headed "Death after section of both vagi," and then an account is given of the phenomena which have been observed to result in different animals from that lesion.

2278. Then your opinion is that it is an experiment which ought not to be resorted to ?—Excepting for the purpose of investigation. It is an experiment which has yielded results of the very greatest importance, and consequently when it has been done previously, it has been done with the best justification.

2279. The result of that experiment has been so clearly established already that it is stated in this book with perfect precision, is it not ?—It is stated with a certain precision ; but it cannot be said that the result of it is fully known already, because there are many points connected with it which are not as yet known, and I cannot say that it is not even probable that it may be performed again, but no one would perform it for the purpose of seeing only the facts which are already recorded and already known. If it was done at all, it would be with reference to some of the facts which are not known.

2280. There is no very clear distinction drawn in the book, is there, as to whether it is an experiment that a beginner might very properly perform for himself or not ?—Well, I cannot say that that is distinctly stated ; for the reason I have already given, that I do not think that any well educated man would think of doing this experiment, excepting for the purpose of investigation, and certainly not for the purpose of merely seeing the facts which have been already ascertained. But let me observe that the amount of pain produced by that experiment is not in the least greater than the pain which occurs in an ordinary case of pneumonia, an ordinary case of inflammation of the lungs. The only serious painful result of the injury is that inflammation of the organs is produced ; and of course we know that that occurs over and over again to animals, and that they do not suffer any great amount of pain. You asked me at the beginning whether it was a painful experiment, and I said at once that it was a painful experiment, and one in which the inconvenience and suffering was prolonged, because in fact you produce in the lungs of the animal an illness of which it eventually dies. I wish to repeat that there are many things stated in this book which are not intended for repetition by anyone.

2281. (*Sir J. B. Karslake.*) Is there anything in the context to show for what purpose it will be necessary, if at all, to repeat that experiment ?—You will find stated in the text what are the physiological facts which have been derived from this experiment ; there is one of them, for example, which comes across me, which is stated here, but which is disputed. With reference to that fact, it being disputed, it is possible, or probable even, that it would be necessary to repeat that experiment again. The facts which are stated as results here are those facts which arise out of the experiment. There are some however which have been questioned recently, and with reference to them it is quite possible that it may be necessary to repeat the experiment.

2282. (*Chairman.*) The book would naturally lead, would it not, a large number of independent inquirers in different parts of the country to repeat for that

Mr.
J. Burdon-Sanderson,
M.D., F.R.S.,
and Mr.
M. Foster,
M.D., F.R.S.

23 Oct. 1875.

purpose an experiment which was admitted to be painful, and certainly causing death in the rabbit in one day, and in the dog in two or three days, and in which anæsthesia could not be employed?—I cannot agree to that for this reason, that the question arises quite independently of the book. The book affords the best and most efficient way of answering it, and that is all that the book has to do with it.

2283. Now on page 320, No. 110, I find "Asphyxia by slow suffocation." Is it desirable that asphyxia by slow suffocation should be resorted to by independent inquirers generally?—Well the subject of asphyxia is one of course of fundamental importance; it has been investigated by experiments lasting over a considerable period from time to time. Now in consequence of the introduction of better methods of research, such experiments as have been made in the past would not be made again. I may allude, for example, to the experiments made by a committee of the Medical and Chirurgical Society, of which I was a member some 14 or 16 years ago. Those experiments were a sufficient number, but they led, as usually happens when committees assemble to make experiments, to very unsatisfactory results. Since that time we have come, by the use of the best methods, to understand the subject of asphyxia very completely. Of course it is not desirable to make experiments with a view of making more certain things which are already certain; but the only way in which one could bring together the various elementary facts which relate to the subject was by giving an account of it in this way, at all events it is the most ready way of doing it. I may answer the question by saying that it would be decidedly improper to repeat painful experiments already made in this or in any other case, for the purpose of determining a fact which had already been determined.

2284. I have taken those instances, rather selecting them as they occurred to me for the purpose of illustrating the view which you have already expressed, and I think you have every disposition to recognize the impression on my part as being well founded, that it would be better that the public should have what are your real views more clearly brought before them than they are already in the preface and other portions of that book; is not that so?—Quite so.

2285. Then coming back from instances to your opinions, you think that there is in this country a tone of sentiment towards the lower animals which would generally prevent wanton or unnecessary pain being inflicted upon them for scientific purposes?—Certainly.

2286. That for the purposes of demonstration to pupils, your own practice and the practice of Guy's Hospital, and so far as your knowledge goes the practice of the other principal schools, is to inflict no pain at all in experiments that are for the mere purpose of demonstration to pupils?—To the best of my knowledge, with the exception of Guy's Hospital and my own school, there is no school in London that teaches practical physiology by experiments.

2287. Then I may take it that in your opinion I have correctly stated what you believe to be the tone of feeling in this country?—Yes.

2288. (*Mr. Huxley.*) Is there no teaching of physiology at King's College?—I ought to have mentioned King's College; but the position at King's College has lately been vacant, and it was on that account that I omitted to think of it.

2289. (*Chairman.*) Then we may say that the only necessity for inflicting pain upon animals at all is where original research is the object?—Yes.

2290. That where original research is the object, it should be practised not by persons inexperienced and incompetent, but on the contrary by persons of the highest experience and competency?—Yes.

2291. That it is a legitimate object for the public and the Legislature to have in view, to secure, if necessary, that such shall be in future the practice in this country?—Yes.

2292. And to take care that some of the practices, which we have public evidence for knowing are resorted to in other countries, shall not be introduced into this country?—Yes.

2293. And for that purpose you are willing, speaking generally, to coincide in the proposals made by Dr. Playfair to the House of Commons?—Yes.

2294. Though, as I understand it, you reserve liberty to comment upon portions of Dr. Playfair's proposals, if you think fit?—Yes.

2295. But that in the main, to the general outline of Dr. Playfair's bill you may be taken to be a consenting party?—Yes.

2296. Now would you allow me to ask you in what respects may the study of physiology be expected to be useful for the advancement of practical medicine?—The utility of physiological study, it seems to me, ought to be judged of, not so much by its direct applicability to disease, as by the certainty which exists in our minds that eventually it will be the guide of practice in medicine; and I wish to emphasize this first statement particularly, not because I am insensible to the fact that there are a great many direct applications of physiology, but because I think that what ought to encourage us above all is that certainty of which I have spoken. And I wish to illustrate that by referring to some of the common diseases, and to some common remedies; for the reason why medicine fails is, that we do not know the nature of the diseases, and that we do not know the mode of action of the remedies which we use in many cases. A most common acute disease is inflammation. With reference to inflammation we have been working at the subject of the mechanism of the disease, for a long time, but during the last eight years very signal progress has been made, in the explanation of its leading phenomena. The most prominent phenomena of inflammation, the so called cardinal ones, are pain and heat, and redness and swelling; and with reference to the last two, we have been until lately unable to give any account of the mechanism of them; and even as regards heat, we have considered heat as a characteristic of inflammation, but until lately we have not possessed an exact measurement of the temperature which actually exists in inflamed parts, or understood the laws which govern the temperature. Then as regards redness we have known about the general fact that inflamed parts were red, but until the last few years we have not been able to explain the nature of the process by which, as soon as a part is irritated, it becomes red, that is, by which it becomes congested with blood. And then again going on to the other point, the swelling, which is another cardinal symptom of inflammation, it is only very lately that we have learned to know what the meaning of that swelling is at all—what it depends upon. We not only know now that it depends upon the passing out of the constituents of the blood through the blood vessels, but we know exactly the mechanism of that process, and have gained the whole of that knowledge entirely by experiments.

2297. (*Lord Winmarleigh.*) By experiments on animals?—By experiments on animals.

2298. (*Sir J. B. Karslake.*) Might we add the word "painful"?—Painful experiments. With regard to experiments on inflammation, even the most simple ones cannot be done without the production of a certain amount of pain; because pain is one of the phenomena of inflammation.

2299. (*Mr. Forster.*) But does that imply pain without anæsthesia that the experiments cannot be performed under anæthesia?—With anæthesia, as regards many of the observations perhaps; but still without anæthesia as regards the process itself. You cannot produce an inflammation in an animal and maintain a state of anæthesia during the whole of the process; it is quite impossible. Then take another disease, namely, the disease tuberculosis. You have here a disease which destroys an immense number of lives every week. With regard to the nature of tuberculosis, until within the last six years we have really known absolutely nothing of the mechanism of the process; I mean the physiological changes which take place in

Mr.
J. Burdon-Sanderson,
M.D., F.R.S.,
and Mr.
M. Foster,
M.D., F.R.S.

23 Oct. 1875.

connection with it. For, as regards this disease and the other which I have mentioned, we have known what you may call the natural history of the disease familiarly for long; we have known, I mean, the aspects which it presents to the clinical observer, to the observer at the bed side; but what we have not known has been the intimate nature of the changes of which the disease really consists. As regards tuberculosis, the leading discovery with reference to its nature was made some half a dozen years ago, by a French observer, M. Villemin, who, although he misunderstood his results more or less, made observations which have led to investigations which have been carried out in all the seats of scientific activity, and which have led to an approach towards a really complete knowledge of the mechanism of the process of tuberculosis. That result is due not exclusively to experiments on animals made with reference to the question, but it was by experiments that we were first led to our fundamental knowledge on the subject. I mean we were enabled to understand the mechanism of the process by being able to produce it in animals. I think it does not need explanation that it is a proof that we have the key to the production of a process when we can reproduce it—when we can bring about the conditions under which it originates It must be understood that this progress was also helped forward by anatomical investigations, particularly with reference to the anatomy of the lymphatic system. As regards this branch of anatomy, the anatomy of one of the great systems of which the body consists, an equally marked progress has taken place during the last few years; and that investigation, although it was anatomical, has necessarily involved making experiments upon animals, because in order to make out the structure of the lymphatic system it has been necessary to produce what we ordinarily understand by disease, that is to say, abnormal conditions of it, in order to be able to trace out its structure; so that in both directions, both the anatomical, and the directly experimental, it has been necessary to put animals under special conditions, under conditions unnatural and disgreeable to themselves, in order to bring out the facts in question. I said before that a very large number of persons died of tuberculosis. Of phthisis we know that about 10 per cent. die of the total number of deaths; but besides these there are certainly more than that number that die of other tuberculous diseases; so that every week in London you have upwards of 200 people in a thousand who die of those diseases. With respect to inflammatory diseases I cannot state positively, but of the remainder the majority is certainly made up of them. There are many other common diseases of which we do not know the mechanism at all, although, as I said before, we know the natural history very well. For example, cancer, we cannot give any such answer with reference to cancer as we can give with reference to tuberculosis. Then again, acute rheumatism is a good example of a disease which we know very intimately, but we do not know its mechanism a bit. We do not know why it follows its course, or why it affects the organs it does affect. It also is a disease which is fatal to a great many lives, and if we had the same information there that we have with reference to the others that I have mentioned, we should be in the way of doing a great deal more good. Then I want to speak of a few remedies. First, I will speak of the influence of cold. Cold is used as a remedy against fever. I do not wish to speak of cold as a surgical remedy, but as a remedy against fever. Long ago, it was the custom to subject people to cold effusion, or to the cold bath, in the treatment of fever, and then that practice went out of use altogether. Now again it is coming into use, but not on the ground that a change of opinion has taken place, but because by means of investigation, by means of experimental investigation too, we know what is the mode of action of cold, and we know what is its relation to the condition which it is intended to cure, namely, fever. We know that in fever there are certain conditions in which the application of cold is injurious, and other conditions in which it is not only beneficial but the only thing which can save life. We have instances, of which several have occurred in London in the last few years, in which persons affected with acute rheumatism have passed into a peculiar stage of fever, which we now know how to recognize, in which the application of cold is the one and only thing which can save life, and by the application of cold life has been saved. This leads me to speak of its influence on fever generally. In fever we have two sets of symptoms; certain sets of symptoms which are dependent upon the influence of the high temperature of the body upon the body itself, and others which belong to the general state of the system; and what we know is, that with regard to those symptoms, those dangers in fever which are dependent upon the unnatural heat of the body, we can do good by bringing down the temperature by external means, but that as regards those dangers which arise quite independently of the heat of the body we cannot do so. Then I would like to speak of another remedy, namely, that of bleeding. It is very well known to everyone, I believe, that bleeding is a remedy which after having been used a great deal has been thrown aside, and again used. For example, at the end of the last century people were afraid of bleeding. It is difficult to say why, but it was so. During the period of the war, and immediately after the peace, there was a tremendous reaction in favour of bleeding, which reached an acme of extraordinary intensity somewhere about 1820, between 1820 and 1830. During that time the number of lives that must have been sacrificed to bleeding is altogether beyond calculation, and it must be remembered that these lives were so sacrificed simply for want of knowledge. Then came influenza and cholera, and they demonstrated clearly that bleeding was injurious by direct experience; notwithstanding which, bleeding, though less used, still continued to be used till about 25 years ago. Now, we know that bleeding is injurious, not because experience teaches us that it is so, for we know that experience seemed to teach our forefathers just exactly the opposite, consequently experience is not a safe guide in a question of that sort, but because we know precisely what bleeding does to the animal organism. We know also a good deal about the mechanism of fever; we know, for example, as regards the state of the blood, that the very same condition which is produced in the blood by bleeding is also produced by fever itself, and, consequently, that by bleeding a person with fever we are just helping to do the mischief which the disease is doing. Under those circumstances the question arises, is it conceivable that we should now fall back again into such a state of things as existed in 1820, that we should again resume bleeding, and begin to treat people as they did at that time? There is no reason why we should not, excepting knowledge. The fact that we know what bleeding does, and the fact that we know what fever is, are the only safe-guards against our falling back into the practices which our forefathers followed. That I think is a good illustration, so far as it goes. Then I would refer to the subject of food. In the treatment of all acute diseases we now attach great importance to food as a means of treating disease; and there again there has been a very great difference of practice. Some of us may remember the time when the starvation practice existed to a very much greater extent at all events than it does now. I will take one item of food, that of gelatine. Formerly it used to be held, that all gelatinous stuffs were the very best things you could give to invalids. People used to have hartshorn and isinglass and all those things, which were considered as among the most important *subsidia* of the sick room. That passed away, and the time came when all these things were condemned as useless. Now we are in a different position. The physiological action of gelatine has lately

Mr. J. Burdon-Sanderson, M.D., F.R.S., and Mr. M. Foster, M.D., F.R.S.

23 Oct. 1875.

been most carefully investigated; these investigations have been carried on at the expense of the Bavarian Government, on a scale of sufficient magnitude, and now we have a mass of the most complete information with reference to the action of gelatine, and many other kinds of food, which places us in this position; on the one hand, we could not possibly come to a state of things in which we should attach such value as our forefathers did to gelatine; on the other, we could not possibly go back to the rejection of gelatine as an article of diet which succeeded that state of things. By science we are put in a position to form an exact and certain opinion as to the value of that particular article of food, and from that position no waves of medical opinion could possibly drive us. Then let me pass to another remedy, namely, alcohol. Alcohol is another agent which is chiefly used as a means of treating fever; and now we know a great deal with reference to it, as to how it acts. The first thing is this, that in fever the main condition, as I mentioned before, is high temperature; I mean that the temperature of the body, instead of being at the normal temperature, about 98°, rises to a temperature of 105° or 104°, and so on. What we know about it is, that in fever alcohol has the effect of bringing down the temperature to the normal state, but that upon the healthy person it exercises no such influence; if you give a healthy person alcohol, his temperature remains exactly the same as it was before (I mean giving alcohol in what we may call beneficial ordinary doses); but if you give the same doses, or suitable doses to a fever patient, you have a special effect produced, namely, the reduction of the temperature towards the normal. All this information about alcohol again has been obtained by experiments on animals, seconded, I must explain, by careful systematised clinical observations on patients; but in all cases of this kind the proper way to begin is by seeing what happens on animals first, and then of course you make the results of the experiments practically valuable by weaving them in with the results of experience.

I wish further to point out, with reference to some of the diseases which I have mentioned, particularly tuberculosis, the most important application which will be made of the knowledge we are gaining will be rather in prevention than in treatment, because our more careful investigations of the processes of tuberculosis only lead us to maintain the opinion, even more decidedly than before, that the process, when it has once begun, is an incurable process; but the application which will be made of our knowledge, as soon as it is complete, and is being made of it now as far as it is complete, will be rather to enable us to know how we may prevent tuberculous diseases. As regards the causes of tuberculosis, what has come out so clearly, both from ordinary experience and from careful investigation is that there are two sets of causes; that we have on the one hand constitutional predisposition, and on the other the exciting causes of the disease, and our investigations with reference to animals will, we hope, enable us to understand the nature and mode of working of both of these sets of causes. First, as regards the predisposition, what we have learned is that certain species of animals are susceptible, others are insusceptible. We know physiologically what are the peculiarities of these animals, what are the physiological differences, if I may so express myself, and this is guiding us to a knowledge of that in which susceptibility really consists; I mean of the anatomical and chemical differences between susceptible and insusceptible organisms. I merely mention this as one line of inquiry. Then as regards exciting causes, we have come to the same kind of knowledge of the exciting causes of tuberculosis. We know, for example, that there is nothing specific in the disease, but that certain external agents tend to originate the process and to keep it going; and our object is to make our knowledge of the nature of those external agents more and more precise. I will endeavour to illustrate that statement by referring to the way in which we should set to work to find out the influence of climate; I mean, for example, the reason why persons are affected by tuberculosis in London, and not affected by it in certain other particular districts. The way that one would attempt to find that out would be this, by subjecting animals to the same conditions which we already know to be productive of tuberculosis, on the one hand in London, and on the other in the other climates in question. This is a kind of investigation which has been already commenced, and there is every reason to hope that it will give us important information. If we learn, for example, that an animal which has been kept in a certain climate, where the air is absolutely pure, if I may so express myself, is under certain conditions not made tuberculous at all, but under the same conditions in London is made tuberculous, we certainly gain very definite information as to the influence of those two atmospheres in the causation of the disease. Of course I am anticipating in giving these examples. I do not mean to say that these questions have been answered, but I am endeavouring to make it clear how they are likely to be answered. The same thing applies to another subject, namely, that of the secondary diseases, which are produced in consequence of injuries, the so called traumatic diseases. We know that a person receives a gunshot wound, or a smash of some kind or other, and that the result of that is that there is local inflammation produced; but, that inflammation may follow a good course, or it may follow an unfavourable course, and give rise to a number of so called secondary diseases, a general involving of the whole system, or the production of secondary inflammations in other parts of the body, such as those which are called pyaemic, and are apt to follow serious injuries, particularly injuries which are attended with great destruction of tissue. All that subject is at the present time receiving an attention in all parts of the world where pathological investigation is going on, which has never been given to it before; and in great measure the reason of this is, that during the war a number of men versed in research were placed with the troops, and that in consequence new facts of a very remarkable kind were observed. These facts have led to further investigations, which have been, in a great measure, experimental; and thus an immense activity of research has been thrown on to this particular subject. I mean the mode in which the secondary results, so tremendously fatal as they are in their character, are produced in consequence of great injuries. That I think is another example showing that we are finding out by experiment in what way such states of things are produced, and how we may confidently hope to be able to prevent them.

2300. (*Chairman.*) For these discoveries of which you have been speaking, has physiology been dependent for its progress upon experiments made upon living animals?—I think I have nearly answered that question already, as far as the various subjects which have been mentioned are concerned.

2301. Under what conditions can experimental investigations be most advantageously made?—With reference to that I should like to point out the conditions which actually exist in physiological investigation just now, and which we hope will exist in future, although that point has been already partly brought out. Until recently investigation in this country, at all events, has been carried out in not a very systematic way. No doubt, as was said at the beginning, an effort is being made to organize research as much as possible. In Germany, as I think I have already stated, that has been the case for some time past, that is to say, that there are a good many persons in Germany whose lives are devoted to science, who hold responsible positions as University teachers, and who are engaged in physiological work and physiological research. In England the professed physiologist has been until recently unrepresented, that is to say, the physiological work has been done by persons engaged in other pursuits at the same time.

Mr.
J. Burdon-Sanderson,
M.D., F.R.S.,
and Mr.
M. Foster,
M.D., F.R.S.

23 Oct. 1875.

Even the late Professor of Physiology in Edinburgh, who was the only professed physiologist in Great Britain until a few years ago, was also a medical practitioner, a consulting physician; that is not now the case, in Edinburgh; for the gentleman who now holds that position is a professed physiologist, who occupies his whole time in that way. At the present time there are three positions in England which are occupied by men who are professed physiologists. There is Dr. Foster's position at Cambridge, mine at University College, and the Brackenbury Professorship at Owen's College, Manchester. I do not know what the conditions are on which all of these appointments are held; but with reference to my own appointment I may as well say that my professorship is held under the condition of devoting myself to original research. The words of my appointment are these: "On condition of devoting to original "research, either in connection with his professorship, "or in any other work of a kindred nature, which "shall be essentially auxiliary to such research, all the "time that can be spared from the work of the "lecture room." In this way there is assigned to anyone holding my position a function which is separate from the function of ordinary teaching.

2302. Is that intended to exclude you from practice?—Yes, it is intended to exclude me from practice. What I want to draw attention to is the organization that this involves, and what that organization ought to consist in. What it ought to consist in is, in the establishment in connection with every school of science, and particularly of chemistry and physics, of a school of physiology, that is to say, chemistry and physics applied to the explanation of living phenomena. It is desirable that such schools should be connected with the systematic teaching of physiology to medical students; but that teaching is not what I mean by a school of physiology. I mean by a school of physiology, not the teaching of students by lectures, but the association of workers under the direction of a head, such persons not being students in the ordinary sense, but men who are themselves devoted to science, either for their whole lives, or for a certain definite period, men who are intending earnestly to engage in research for a certain time. It is in this way, I think, that physiology ought be studied, and the more it is studied in this way the better. In such schools of physiology it is clear that the work which will be done will be in a great measure experimental, because we cannot make progress without experiments of one sort or another, painful or otherwise. The question arises what the bearing of that will be upon the matter which we have now before us, namely, the question whether abuses are likely to arise in connection with such schools, or whether on the other hand it is not the case that the existence of such organized schools will tend to check and prevent abuses. I say that abuses are not likely to arise in connection with any such institution, because, in the first place, it is managed by a person who is publicly responsible, and, secondly, because the physiological school is a part of an institution which is governed always, as in the case of King's College, or in the case of University College, or Owen's College, Manchester, by a committee of men who are not in the least likely to tolerate anything which is objectionable in the conduct of such an institution; and I may say in passing that one practically finds that in every such body of men you will always find some men who have strong humanitarian feelings, so that there are always men who are, so to speak, on the watch against any abuses which are likely to arise in connection with such institutions. It is obvious that that method is the best for science. It is perfectly clear that for the sake of science it is most desirable that the whole thing should be methodized, and that all researches, if possible, should be made in this methodized way, and under the superintendence of persons who are themselves skilled, and with the assistance of others who are also skilled. But in England I do not think that we can put a stop to individual action. I cannot conceive that it is possible that we should not have men who are working in science quite independently. We know that in England individual action in all things is the national tendency, and it is just the same in science as in other things. A great deal of scientific work is necessarily done by persons who choose to work by themselves and who do not want direction, and do not wish for direction; and we have plenty of examples to show that that sort of individual work is very often productive of extremely valuable results. Of course, the objection to that is this, that there is not the same guarantee for verification; for everything that is done in an institution for research is verified, not only by the supervision which it undergoes, but by the presence of other persons who are engaged in other branches of research, and whose testimony is of great value.

2303. I think you have said that there is now an effort made to organize physiological inquiry much more systematically than it has ever heretofore been organized in this country?—Yes.

2304. That the most efficient mode of promoting such inquiry would be by institutions of a public character, like your own institution and Guy's Hospital and that of Trinity College, Cambridge, and so on; and that the publicity which would be connected with such institutions would have a very good effect for science, inasmuch as it secures verification of the experiments which might be doubtful if they were in the hands only of private persons?—Yes.

2305. That implies, does it not, that in its organization the influence of publicity will, to a great extent, prevail?—The influence of organization, I should rather say.

2306. So that anything that would happen in such institutions will of necessity be known to the gentlemen who conduct those institutions?—Yes.

2307. And being known to so large a number of persons, we may take it that in truth public opinion will come to bear upon them?—Yes.

2308. And that that public opinion will, in your judgment, be a great security against those abuses which are the particular subject of our inquiry?—Yes.

2309. You think, however, as I understand you, that in this country you cannot altogether repress individual inquiry, and that something must be left to individuals?—Yes.

2310. But you think also that those individuals ought to be subject, I presume, to the same general limitations that the institutions would be subject to, namely, that public opinion should influence and direct their proceedings, in reference both to science and to humanity?—Yes.

2311. Therefore that some legislative provisions, if they extended to these institutions, might reasonably also extend to any private inquiries?—I do not know whether the question suggests what I should like to say, but I should like to make this statement with reference to legislation in general. That so far as the institutions to which I have referred are concerned legislation is certainly not necessary, because there is no influence which legislation could exercise of a beneficial character upon those institutions, which is not already exercised by the organization under which they are placed. I refer to the two facts that they are under the direction of committees, or bodies equivalent to committees, containing men of position in society; and on the other hand that they are under the immediate direction of educated and responsible men.

2312. So that without thinking that for those institutions legislation is necessary, you think that such legislation as you were yourself a party to, proposed by Dr. Playfair, would not in any way interfere with the efficiency of those institutions?—I would answer that question, subject to the comments which I should like to make upon his bill, taking that as a sort of example of what I suppose legislation might be expected to be.

2313. As I understood you before, reserving to

Mr. J. Burdon-Sanderson, M.D., F.R.S., and Mr. M. Foster, M.D., F.R.S.

23 Oct. 1875.

yourself to make some observations upon the details of the bill, to the general scope of it; you were an assenting party?—Yes.

2314. Now perhaps if you wish to make any particular remarks on the bill, you will be good enough to do so?—There is one point I should begin with, namely, the expression in clause 2, "new scientific discovery." That was not in the sketch of the bill that I saw, and that does not admit of any definition at all to us. A "new scientific discovery" has no definite meaning in relation to research. It is the object of research, not merely to make new discoveries, but to establish the truth, and to develop discoveries which are already made; and therefore what is really required there is something of this sort: "Any person for the purpose of investigation," or something equivalent to investigation, or "scientific investigation," it does not matter what expression is used, but it must be something to which one can attach a *bonâ fide* meaning; I mean one that one has not to take a great deal of trouble to assign a meaning to. The question what a new discovery is or what it is not is a question which might be discussed endlessly. One man might say, "This was anticipated a hundred years ago," and you would find just as many people who would say "It was not known at all; we were absolutely ignorant of it before;" because one would assume a mere vague expression of a thing to be an adequate statement of it, whereas the other would expect an exact statement of it and in this way there would necessarily be a constant conflict of opinion between people who spoke exactly and people who spoke vaguely. I do not see how you can possibly get over that, except by using some expression which would imply the *bonâ fide* intention of the investigator. Any investigation which is done *bonâ fide* for a scientific purpose, for the purpose of investigation, would be a proper investigation to make; and any investigation which was made without purpose would be, of course, not an investigation at all, and certainly not a scientific investigation.

2315. A short time ago, in reference to one of the instances which I proposed to you from your book, you said that to repeat a painful experiment which had already proved that which was the object of it, for no new object, but merely for a repetition of the same truth, would be improper?—Yes.

2316. I do not understand you to depart at all from that opinion, but merely to say that you think these words in the bill before you are too narrow, and would tie down an experimenter more than would be necessary to carry out the intention of the person who drafted the bill?—Yes.

2317. (*To Dr. Foster.*) You have had the advantage of hearing Dr. Sanderson's evidence. I would ask you if you have in the main agreed with it?—I have in the main; probably some of the answers I should have given would not have been exactly those which Dr. Sanderson has given.

2318. Does it occur to you to specify any particular instances?—No, I think I could not do that.

2319. Then I may take you as in the main agreeing in the evidence which has been given by Dr. Sanderson?—Yes. Perhaps one point in which I would not go quite so far as Dr. Sanderson would be in the matter of the necessity for legislation.

2320. Would you be so good as to state what is the point of difference which you wish to bring out?—Simply that I, so far as my experience goes in this country, think that there have been no abuses in physiological inquiry, and I think that that humane sentiment to which Dr. Sanderson referred, might be of itself trusted entirely to prevent any such abuses taking place.

2321. But supposing that in the minds of the most competent persons, and the most elevated persons, and of those with whom you generally are most acquainted, there is that humane sentiment, would you entertain an objection to taking measures which might prevent physiological experiments falling into the hands of other people of less exalted sentiments?—Certainly not. That was not the point on which I differed from Dr. Sanderson, but on the other point; I have no objection to legislative interference. I only disagree with him so far as I understood him to say that he thought it was desirable or necessary.

2322. Let me ask you some questions as to one or two of the experiments in this handbook which are given under your name. I see on page 395 you begin by saying:—"Introduce beneath the skin of the "back of a strong frog a drop or two of a solution of "urari?"—Yes.

2323. Do you entertain the opinion that urari is an anæsthetic in regard to frogs?—What I would say is this: that there can be be no doubt that urari suspends the functions of the motor nerve trunks; there also can be no doubt that it does not affect to anything like the same extent the sensory nerve trunks; those two things are quite certain. Bernard and others with him have from that and other facts about urari drawn the conclusion that the central nervous system, as distinct from the sensory nerve trunks themselves, was not affected at all by the poison. It would be quite possible of course for the poison to affect the sensory nerve trunks and not affect the central nervous system; and on the other hand, for it to effect the central nervous system and not the sensory nerve trunks. From my observations on urari poisoning in the course of some two or three years, I had always been led to doubt very much the immunity of the central nervous system from the action of urari, while admitting, of course, that the sensory nerve trunks were not affected by it; and most physiologists, I think, will agree that by large doses of urari the central nervous system is certainly affected, that is to say, that although action may take place in the sensory nerve trunks, that sensation for instance might begin there, it would not be developed as a conscious sensation in the central nervous system; and from some experiments which were made by Mr. Yule of Magdalen College, Oxford, comparing two frogs, one under urari and the other not under urari, there seemed to me to be very strong evidence indeed that urari does, even in moderate doses, prevent voluntary movement or volition; and if it prevents volition, it seems to me that the arguments are extremely strong in favour of the view of its doing away with consciousness. Now those experiments can be carried on on in a frog; and similar experiments on other invertebrata have been carried on by Dr. Steiner, of Halle, all pointing to this conclusion, that urari does act in some of these animals primarily upon the central nervous system in destroying volition, and with that, one infers, taking away consciousness. As far as I know the experiments have not been carried on in the case of warm-blooded, quickly breathing animals, and at present one is uncertain as to whether the action of urari has the same effect upon them as it has upon frogs, because the method of observation which is employed upon frogs cannot be employed upon the warm-blooded, quickly breathing animals.

2324. I infer from what you say, that in your opinion, urari does destroy consciousness in a frog?—Yes.

2325. You differing in that particular from Claude Bernard and from the physiologists of the continent in general?—Yes.

2326. And you have set forth the experiment mentioned in this book under that opinion?—I beg your pardon, No. This book was written before I arrived at that conclusion. You ask me my opinion at present. Those experiments of which I have been speaking are recent. When this book was written I simply was in doubt about the action of urari upon the central nervous system, and was not prepared to give, what I think I may now say I can give, tolerably conclusive evidence of the view that urari does destroy the central nervous system.

2327. Then this book was written under the impression that urari did not?—This book was written

Mr. J. Burdon-Sanderson, M.D., F.R.S., and Mr. M. Foster, M.D., F.R.S.

23 Oct. 1875.

under the suspicion, under the belief from several facts, that urari did destroy the central nervous system, but not with what I believe to be the tolerable certainty which I have at present.

2328. Then the book was written under a doubtful impression on your part whether a frog into which urari had been infused was conscious of pain or not?—Yes.

2329. And when you said that they should get "a strong frog" and introduce a drop or two of a solution of urari beneath his skin, you were very doubtful whether he would be conscious of pain or not?—Yes.

2330. And you took a strong frog, I suppose, because you thought he would be better able to bear pain?—No, but because he would better manifest the phenomena of the poison.

2331. At any rate it was only a doubtful opinion of yours that he would be relieved from pain?—Yes.

2332. Now these experiments upon frogs are very painful ones in their nature, are they not?—Some of them; not all of them necessarily. Might I just make a preliminary statement, before you ask me any other question, as to my purpose or what I had in view in writing these directions? If you turn to the preface on page 341,—I mean to the introductory remarks,—you will see that I say "Such observations "and experiments as the student may be reasonably "expected to perform for himself under due super-"vision." My idea was that these directions would be used in a physiological laboratory, under the direction of a competent supervisor, and the object of the form in which I put the observations was to enable the student to go on with the operation for a certain time, while the supervisor passed from him to another student, to facilitate the performance of the operations under the demonstrator. I have therefore taken no special care to point out exactly what operation should be made by this or that class of students. One would have students of various classes; some whom you would not desire at all to repeat any of these experiments; some to whom you would entrust a certain number; others to whom you would entrust a larger number, and in whose case the supervision need not be so exact and so complete as in the case of others. Consequently I was not so careful as otherwise I might have been. I was not particular. I did not take particular care to insist in every case upon the introduction of anæsthetics. I put them in several cases, but I was not careful to put them in all. Now in this particular case my own practice, I not feeling certain about its action on the central nervous system of a frog, was to introduce with urari a certain quantity of morphia, which would not materially affect the general result of the experiment, but would make it, one would then feel satisfied, certain that the animal was suffering no pain whatever.

2333. Would you allow me to ask you, do not you think it would have been better, with regard to the persons for whom this book is intended, and who are described in the general preface as "beginners," to specify a little more completely that degree of anæsthesia which you yourself thought it right in your own practice to produce?—Yes. I think, supposing that I had to write the work over again, I should be more careful.

2334. And that it would be desirable that, if possible, the communication of your present opinion should be circulated as generally as the book itself is circulated?—Perhaps it would be.

2335. And that would apply also to the other experiments which are upon pages 396 and 397?—Yes. May I say that, for instance, the experiment on page 396, I think, is not so painful as one might perhaps be led, on first reading it, to imagine. The operation itself is conducted under chloroform. After the operation has been performed, the amount of paid felt by the animal while the urari is acting is not very great, because it shows no signs of pain before the urari is administered.

2336. I do not at this moment see in this experiment any reference to chloroform; I was speaking of Observation 3?—I thought you were speaking of Observation 2 on page 396.

2337. I asked about Observation 3 and Observation 4. You have already stated, you know, and it will go to the public, that you yourself did use what you believe to be complete anæsthesia, and that if you had to write the book over again you would state to others what you do yourself?—Yes.

2338. I ask you whether that does not apply also to pages 396 and 397?—Observation 2 also comes into page 396, and there chloroform is suggested; and in my own mind I concluded that the chloroform would be given in the perfectly corresponding Observations 3 and 4. I thought it was unnecessary in Observations 3 and 4 to state that chloroform might be given, because I had done so in Observation 2.

2339. (*Mr. Erichsen.*) You wrote the book very much as one writes a book on operative surgery, where it is supposed that anæsthetics are to be given, and yet anæsthetics are never mentioned?—Yes, I wrote a great deal in that way. I wrote first without putting in the anæsthetics, and then afterwards I put in the anæsthetics. If I am to explain how the matter came about in these cases of omission, I may say that first of all I remember writing several of these observations without stating that chloroform was to be given, because I took it for granted that chloroform would be given. I did not go into that detail in the experiments; I put the anæsthetics in in some, and omitted them in these two.

2340. (*Chairman.*) Then may I take it generally, without going into individual cases, that you entirely agree with what we have had stated by other teachers, that for purposes of demonstration complete anæsthesia may be secured?—Where painful operations are performed.

2341. That where an operation, in itself painful, is resorted to, complete anæsthesia may be secured?—That is in cases of demonstration. I make it a practice in cases of demonstration to give such demonstrations only as those in which anæsthesia can be applied, where distinct pain comes into the operation.

2342. And you agree in all that has been said so far as this, that it is so in your school, and ought to be so?—Yes.

2343. And do you agree in the other observation, that—speaking now not of toxicology, the introduction of disease into the frame of an animal, but speaking of surgical operations—the number of those which need be painful, and without anæsthesia, is comparatively very small?—Yes.

2344. That in others the pain may be and ought to be very much diminished?—Yes.

2345. That is to say, the most painful parts of the operation being performed under chloroform?—Yes.

2346. And that as far as you know and believe the sentiment, both of the teachers and also of the pupils, in this country would be and is in favour of the utmost tenderness in dealing with animals made use of for the purpose of experiments?—As far as I know.

2347. You thoroughly believe that?—As far as I know.

2348. You object to legislation, not on the ground of any mischief that reasonable legislation would introduce, but, as I understood you, only on the ground that in your belief it is in this country unnecessary; is that so?—Yes. There would be some inconveniences attaching to legislation, but I think also that there would be even for physiology some advantages, and that the one may be counterbalanced against the other. The difficulties, if I may say so, would apply with reference to the private individuals; those, I think, are small in number, and probably decreasing. I think that the nature of physiological experiments is such that the best of them, and probably a large number of them, can only be conducted in a physiological laboratory. I do not place any great stress upon that objection to legislation, but I say on the whole that I object to it chiefly on the ground that it is not needed.

Mr.
J. Burdon-Sanderson, M.D., F.R.S.,
and Mr.
M. Foster, M.D., F.R.S.

23 Oct. 1875.

2349. But supposing it to be needed for private persons, and not to be prejudicial in the case of physiological laboratories, you would not I suppose see any very great objection to it?—I think it would be an objection if private individuals were prevented from following physiological experimentation, but I say that I do not lay great stress upon that because they are few, and probably will become fewer and fewer year by year.

2350. The restrictions which you yourself place, and which all those with whom you are acquainted place upon the practice in these public institutions ought, I presume, to be placed by private individuals upon their own practice?—Yes.

2351. And if there were reason to suppose that there were cases in which they were not so placed by them, the public sentiment might be allowed to express itself in regard to them in the form of some provision which would enforce those restrictions, might it not?—Yes.

2352. (*To Dr. Burdon-Sanderson.*) Have you anything else to say upon the bill introduced by Dr. Playfair?—First as regards the principle,—and what I mean by the principle of the bill is the principle of a licence,—I cannot see any objection to the principle of a licence, because I know very well what the working of licences is in other matters for which people are licensed, and I know that there is nothing in a licence which is oppressive, there is nothing objectionable in having to obtain a licence for any lawful purpose, and no particular inconvenience attending it, unless it were made inconvenient by the conditions; so that there is nothing objectionable in the principle of a licence to do this act more than to do anything else. Then I should like to say something about a point which is not referred to in this bill, namely, the question of inspection. There is no provision for inspection in this bill, and I have very carefully thought over that question, and the way in which any inspection could be carried out. I cannot see that any inspection is possible. There is no example of a similar inspection of any other kind that I am aware of, and I do not see how the functions of an inspector could be usefully performed; and I am quite certain that it would lead to bad results if there were any appointment of inspectors, because of course in any institution (I am speaking first, of the effect of inspection upon institutions) no inspection would give any guarantee whatever as to what happened when the inspector was not present; and the very fact of inspection would lead to a spirit of opposition on the part of subordinates and servants, and in that way a tendency to concealment would spring up, which would certainly be injurious to the interests of humanity. Then as regards the keeping of a list of the animals, that I believe has been proposed. As regards that again it would be impossible to carry it out with any good effect or result. In the first place, because the animals that happen to be there may be intended to be used not for experimental but for anatomical purposes; and then secondly, with respect to some of the animals, as regards frogs for instance, it would be altogether futile to attempt to keep a record of them, those animals I mean that are used in much larger numbers than others, and which are used partly for anatomical purposes and partly for experimental purposes; you could not possibly pretend to keep anything like an exact register, and an imperfect register would be merely a temptation to carelessness and inaccuracy. So that I really do not see that any good could be got by that mode of exercising supervision.

2353. We were told yesterday by some eminent teachers from Guy's Hospital, that everything at Guy's was open to the Society for the Prevention of Cruelty to Animals if they liked to come and see, and that there were no secrects of any sort?—Yes.

2354. I understand you to have the same opinion as was expressed by them on this point?—Just the same. I may mention with reference to my own demonstrations, that whenever demonstrations are done, the time for doing them is written up on the black board; so that if any gentlemen should wish to see them, they might come. It may be perfectly well known to everybody, the board hangs in the corridor, and it can be known that something is going to be done relating to a certain particular subject.

2355. (*Lord Winmarleigh.*) Are the public admitted generally?—Any person, I believe, can walk into University College; certainly anybody could go in there without any difficulty.

2356. (*Chairman.*) May I understand you then to mean that, agreeing in the principle laid down by the gentlemen from Guy's, that perfect publicity should be allowed in all particulars, your objection is to the particular method of securing publicity which has been proposed by some people, namely, an inspector?—Yes.

2357. (*Mr. Hutton.*) May I ask if what you stated just now about the notice on the blackboard applies to the laboratory, or only to the large classes?—That applies only to the fixed lessons. But I may mention that these lessons, when an experiment is made of the kind I was describing before with anæsthetics, are not given with the general systematic course. It is a thing which is arranged beforehand, and the number coming to such a lesson would be relatively small.

2358. (*Chairman.*) But I understood the evidence that we had before to go to this, that there was nothing whatever done within the four walls of the place that was not perfectly open for the public to know, if they wished to know it?—If they wish to know it, certainly. I do not, of course, mean to say that we expect to be intruded upon at work.

2359. (*Lord Winmarleigh to Dr. Foster.*) In talking of the private practice of experiments, you say that the private practice has hitherto been small, and in all probability will become still smaller, have you any idea what the amount of private practice is at the present time?—I think I only know one person who is not connected with a laboratory who is making actual experiments—One person in England, I mean, who is making experiments not in a laboratory.

2360. (*Chairman.*) Who is that?—That is Mr. George Henry Lewes.

2361. (*Lord Winmarleigh.*) And you do not think that in any of the great towns of England at the present moment any private experiments are being made by the medical profession or other parties?—Although there are not regularly organized laboratories in the large provincial towns they have professors of physiology there, who probably have small laboratories.

2362. I mean outside of the great medical schools?—I do not know of anybody, and I have no reason to think that there are any number of experiments being carried on by such persons.

2363. You do not think that even in those medical schools not connected with London these experiments are made without the proper superintendence, and a proper restriction upon cruelty?—I can only say that I have not heard of anything which would lead me to think that such did take place.

2364. (*To Dr. Burdon-Sanderson.*) I will ask you a question with reference to this matter. I see that you are the editor of the book before us. Have you any knowledge of the circulation of the book?—The number of copies that have been sold now I am afraid I cannot give any very exact information about.

2365. But is it a large number?—At present I do not think it is. I do not think that it is selling now to any great extent. It is entirely in the hands of the publisher, and no second edition has appeared.

2366. You have no control over it?—No control over it.

2367. You are aware, I daresay, that a great deal of the feeling which exists now in the public mind upon the subject has been caused by this book?—I am very sorry to learn it. I have only learned it very recently.

2368. It has been admitted by yourself and by Dr. Foster that certain mistakes have been made in the publication which might lead to an erroneous opinion on the part of the public. Could you suggest

Mr.
J. Burdon-
Sanderson,
.D., F.R.S.,
and Mr.
M. Foster,
.D., F.R.S.

3 Oct. 1875.

to the Commission the best mode of correcting that, because I think you admit there is no doubt that an erroneous impression has existed in the public mind from a little want of sufficient explanation in the book as to the mode in which the experiments can be made?—Some step that the Commission could take, or that could be taken by others, do you mean?

2369. Whether it could be taken by yourself or by the publisher, or in any way, to correct the very erroneous impression which you maintain exists in the public mind as to the practices in the great schools of physiology?—A plan has occurred to me, which in fact I ought to have carried out perhaps before, namely, that we might prefix to this book the resolutions which are embodied in a Report of a Committee of the British Association which I was a member of, and took an active part in, with reference to this very question. If it was thought that that would accomplish what is required, it would be very easy, of course, to circulate pretty widely a statement of that kind, and also to have a copy of that report appended to the book, or placed before the title page, or something of that sort.

2370. Would you, as the editor of the book, feel any objection to our making a pretty strong expression on that point, supposing the Commission thought fit, that it was an error in the circulation of the book?—Certainly not, if the statement did not go beyond what we have admitted. If it could be made in any way that would express what I have said on the subject, of course I should not have the slightest objection to its being made as public as possible; I should be glad that it should be made public.

2371. I am sorry, after the very interesting description you have given us, to bring you back to any of the experiments; but there are two to which I would call your attention. One is at page 174, an experiment by Dr. Durante. It is to this effect: "In a " rabbit two small incisions are made across the " course of the external jugular vein, one near the " clavicle, the other near the origin of the vessel, " great care being taken not to go down deeper than " is necessary in order to see the vessel through the " fascia. A small needle is then passed under the vein " near the proximal incision, in a direction at right " angles to that of its axis, and corresponding to that " of the incision, but deeper. A second needle is then " laid in the course of the incision, and drawn tightly " towards the first by a ligature at either end, by " which means the blood current is entirely arrested, " while the coats of the vein are absolutely protected " from injury." Then it goes on to say, "After the lapse of a couple of days," and so on. Now in that instance is it possible that that animal having gone through what is evidently a very painful operation, could be kept for a couple of days without suffering extreme agony?—It certainly is perfectly possible. Although that manipulation seems to be a very severe one, it really was not a very severe experiment, because the irritation which is produced by passing a fine needle behind a vessel, if it is done with any moderate amount of skill, and then enclosing the vessel between the needle and the ligature, as directed here, is a method which is used in surgery, and is certainly not attended with any great amount of pain. In fact the presence of a needle in the living tissues we know very well does not produce much irritation. But, however, that is not the only answer that I would make. I would go on to say that this is purely an experiment of research, and that one would never dream of repeating it, excepting for the purpose of proving the fact. It affords the clearest, so to speak, and sharpest and best proof of the particular fact which it was made to illustrate that really can be given. And the history of that paragraph is this, that this experiment was made by Dr. Durante, in my own laboratory, and in that way it happened to come into the statement of the experimental basis of the conclusion arrived at with reference to the cause of the coagulation of the blood.

2372. I have gone through these cases, but I have not observed that any explanation, such as you have now given, is included in the book itself?—I am afraid not. The point to be remembered about that is this, that in the book there are two sorts of experiments given. There are a certain number of experiments which are suitable for repetition, because they are experiments which might be made under anæsthetics. There are other experiments which may be considered merely basis experiments, that is to say, experiments by which certain important truths are, or have been, simply demonstrated in the sharpest and best way. Various people have investigated this question, for example, of the influence of the living vein upon the blood in the prevention of coagulation. It was required to put down an experimental statement of the facts upon which our conclusions with reference to that subject are founded. To serve for that purpose this, which was the best form of experiment, as it appeared to me, which had been made, was related as an expression of the experimental basis for the statement with reference to the action of the vessel in preventing coagulation. There clearly ought to be in the book a distinction between experiments which owe their value to being records of facts upon which a truth is based, and on the other hand experiments which are intended to be used as means of demonstration, so to speak, or as patterns for researchers; because supposing that a man is investigating not this question but some allied question, in which a similar method would be applicable, he would naturally take a description of an experiment like this, not as his guide, but simply as a point of departure, so to speak; he would modify the method to suit the particular question which had to be investigated.

2373. (*Mr. Huxley.*) Would you be so kind as to say how long after an operation of that kind the rabbit took its food freely, and whether during the two or three days afterwards it showed the slightest sign of objection to its food, or any sign of illness?—In this case certainly not; the rabbit is not in the slightest degree affected by the introduction of a needle under a vein.

2374. (*Lord Winmarleigh.*) That for the number of days alluded to in this experiment he did not show any signs of having suffered any pain?—Certainly not.

2375. Was the rabbit killed after the experiment?—Necessarily; because the point was to see what the structural changes were in the vein.

2376. (*Mr. Forster.*) It would not be a fair impression then to suppose that the animal died in consequence of the experiment?—No; it would have lived to this day so far as the experiment is concerned.

2377. (*Lord Winmarleigh.*) At page 176 this experiment is mentioned as having been made by Mr. Schäfer:—"The following experiment devised by Mr. " Schäfer which has been repeated a great number " of times in the laboratory of University College, " proves this much more conclusively and satisfactorily. " A glass tube, three or four inches long, is drawn " out at one end into an arterial cannula, of the usual " form and of suitable size. A frog having been " secured in the usual way in the prone position, the " heart is exposed, and the right aorta ligatured. A " clip is then placed on the left aorta at its origin from " the bulb. The cannula is then inserted and secured " in the left aorta, and the tube supported vertically " by a suitable holder. This done, and the clip " having been removed, the blood is allowed to flow " into the tube." It then goes on to say this, "It " rises to a height which varies according to the vigour " of the animal, and the quantity of blood which its " vascular system contains, the blood column oscil- " lating with the contractions of the heart." Now if this is done under anæthesia, does a vigorous animal demonstrate more clearly than a weak animal when under anæthesia any experiment?—With regard to this experiment, the only difference between the result in a vigorous animal and in an other animal would be that the column would be higher; the result

Mr.
J. Burdon-
Sanderson,
M.D., F.R.S.
and Mr.
M. Foster,
M.D., F.R.S.

23 Oct. 1875.

would not be modified in its character in the least. But the moment that the thing has been done, there is no reason for the animals continuing to live at all, and that is the actual case in this experiment. It is a very instructive experiment, and one which I do every year. It is one which must be attended with extremely small suffering to the frog; the destruction of the nervous system can be done intercurrently in the experiment.

2378. You think that even without anæsthesia this experiment can be done without any great suffering to the animal?—Yes, I used a strong expression earlier in my evidence about using chloroform with frogs, namely this, that it would be "absurd" in many cases; and so it would, because the difficulty of getting a frog under chloroform is so considerable, and the period which it takes to kill a frog in fact in the way which is described there, though it is somewhat elaborate, is still very short; because the whole operation consists in introducing into the principal artery of the body a tube into which the whole quantity of the blood of the animal flows. Of course as soon as that is done the thing is over, and the whole of that process lasts a very short time.

2379. (*Mr. Forster.*) When you say a very short time, how long a time would you be in killing the frog?—I suppose that the whole thing would be over in the course of about ten beats of the heart. The whole quantity of blood or the greater part of it in the circulation would in that time have passed out of the heart into the tube. Of course the preliminary part takes a certain time, namely, the securing the artery and introducing the tube; but taking it altogether, the time is really very short; and besides I must clearly explain that I entertain a most distinct conviction that the exposure of the heart of a frog is not attended with any, excepting a very slight amount of suffering; and I am quite willing to enter into that point if it is wished.

2380. (*Lord Winmarleigh.*) Upon that subject of the suffering of a frog, may I ask what are the chief reasons which have induced the professors of physiology to suppose that a frog does not suffer pain under curari; whereas it has been decided that it is possible that larger animals may suffer?—In the first place those experiments which Professor Foster referred to made by Dr. Steiner; and secondly, these investigations of Mr. Yule's; and thirdly, some others which have been made by Dr. Brunton and others.

2381. What are the symptoms which induce you to believe that in the larger animals curari does not affect the sensory nerves, because I think you said in the larger animals it was supposed not to affect the sensory nerves?—That is quite correct; we know that both in the frog and in the larger animals the sensory nerves are exempt from curari in ordinary doses; but the evidence that we have, as Professor Foster explained, goes to show that the central organ itself is acted upon by curari in the frog, because we are able to show that, for example, if you exclude a certain portion of the muscular system from the action of the curari, the animal does not use those muscles any more than it does the rest; showing that it is not as you might suppose that it shows no evidence of pain, because it is not capable of using its muscles, but because it has no desire to use them.

2382. Generally speaking does a frog demonstrate the same pain in common operations without anæsthesia that a larger animal does?—I am particularly glad that you have asked me that question, because it is one that I wish to answer. The evidence of pain on the part of the frog is excessively small. The mode of expression of pain which a frog has is entirely what it does with its muscles; I mean the motions of its limbs and the motions which it makes for the purpose of getting away; in fact, the only characteristic sign of pain or discomfort that you have in the frog is that it jumps off. With respect to that we have exactly the same evidence of pain in a frog which has been deprived of its hemispheres as we have in the other frogs; because the very same excitation of the skin, a pinch, for example, of the skin, will produce exactly the same reaction in the frog which has been deprived of its hemispheres as in the normal frog. It cannot express its feelings in any other way, and it expresses them just as perfectly when it has been deprived of its hemispheres as it does with its hemispheres. Then the objection may be made, "Oh, but it is possible "that the frog feels without its hemispheres, that it "has other organs by which it feels." The answer to that is, the only reason that you have for supposing that the frog feels at all is that we feel under the same circumstances. We know that if our hemispheres are taken away we feel nothing; and we know with regard to other animals of which the expressions of pain are distinct, that they also, in the absence of their hemispheres, feel nothing. Consequently the very same ground which we have for thinking that the frog does feel applies to the other question, whether or not its feeling is dependent upon its hemispheres. If it feels at all its feeling must be dependent upon the entirety of its hemispheres. If we prove that it affords the same signs of pain when it is without its hemispheres that it does with its hemispheres, we prove that those signs are worth nothing as a sign of pain.

2383. If we are deprived of our hemispheres we die?—We die; but the frog does not; it goes on living. You can go on feeding it (it has not sense to feed itself), and it is just as healthy as another frog.

2384. Does not that show that it is not an argument one way or the other?—Quite so; I say that the evidence is negative as regards the frog.

2385. And you cannot produce any evidence to show the reality of the frog not suffering?—Neither way; we cannot prove it either way. Of course, we believe that as the frog has a nervous system which is very much below ours in activity, and as particularly its organs of sensation are very much smaller relatively than ours, we may take it for granted that in proportion it feels less; but we also take it for granted that it does feel to a certain extent.

2386. May I ask you, do you in your school make experiments frequently upon the larger animals?—For scientific purposes you mean, I suppose. We use very much fewer animals than people imagine; we use comparatively few.

2387. What are the animals besides frogs, dogs, and rabbits that you experiment upon the most? Of the larger animals, which do you perform your experiments upon?—I may say none almost. A cat might be substituted for a dog for certain purposes.

2388. Do you believe that experiments are made in any of the other schools upon any other animals, frequently I mean, than those you have mentioned, dogs, rabbits, and frogs?—I think cats are used occasionally when they are suitable for the purpose. There is a set of experiments I should rather like to mention made upon cats, namely, those made by Dr. Legg. I am not in the habit of reading the papers, but I believe that those experiments have been very severely commented upon. With reference to those experiments, the object for which they were made was an extremely definite one and a very important one. The experiments in question were with relation to the effect of high temperature (I think those were the ones most objected to), on the tissues of the body, that is to say, the changes which certain organs, and particularly the liver, undergo under the influence of high temperatures. I have got here the paper, and if you look at it, you will find that none of the temperatures were higher than are sometimes met with in fever; and consequently it was no very extraordinary suffering to submit the animal to a temperature of that kind, of course that being the temperature which was required for the purpose.

2389. I will not go farther upon that. You stated I think that it was impossible to carry out inspection effectually. Do you see any reason why the heads of the different schools of physiology should not be themselves made equally responsible as the man who might be appointed inspector?—I do not see any

Mr.
J. Burdon-
Sanderson,
I.D., F.R.S.,
and Mr.
M. Foster,
M.D., F.R.S.

23 Oct. 1875.

objection to that, it might be implied in the conditions of the licence.

2390. You yourself, for example, might be made responsible for the conduct of the operations in the school over which you so ably preside?—One would not like to be made liable to penalties for any impropriety of conduct on the part of others in experiments they might make. All one can say is, "I will do the best I can to prevent anybody doing what is wrong;" but to make me responsible for an act, and that a penal one, done by another would be going too far I think.

2391. You are acting at the present moment, I presume, under a licence?—A licence to teach, but not to conduct investigations.

2392. But you see no objection, you say, to any licence being issued to the head of a school, a professor who should teach physiology under certain responsibilities?—Provided that they were not penal responsibilities. I mean to say that I could not go beyond, in the way of responsibility, saying "I will "do my best to prevent anything being done that is "wrong."

2393. (*Sir J. B. Karslake to Dr. Foster.*) I understand you to say that in your judgment there ought to be no licensing either of laboratories or of private individuals?—I said that I thought it was not necessary. I did not go so far as to say there ought not to be any licensing; I said that I did not see the necessity for it.

2394. Now supposing the necessity either exists at the present time, or should exist hereafter, have you at all determined in your own mind the sort of license which should be given to that individual?—No, I have not; I feel a great difficulty on that question.

2395. Have you at all determined in your own mind whether it would be expedient that a private individual who might be perhaps a man of great eminence, engaged in physiological research, should be bound to state what experiments he proposed to make, and what the object and result of those experiments were, before he was allowed to perform them?—I think he could hardly do more than indicate the *line* of his research. Because directly you begin an inquiry you begin in one line—you begin, I mean, with one set of experiments; and at once something occurs which takes you off in a completely different direction. No one can possibly declare completely beforehand what are the experiments that he wishes to make; and if he began an inquiry, having made the experimetns which he said he was about to make, and in the middle of those experiments a diverging line occurred to him, and he then had to wait till he had a further license to go off on that said line, physiological investigation would be impossible.

2396. If any license were to be granted at all, should you propose that it should be a general license to practice vivisection with a view to science?—I think it must be a general license; I do not see the possibility of defining any special license.

2397. (*Mr. Hutton.*) You say that you do not see the slightest necessity at present for any kind of inspection or restraint, on the ground, as I understand you, that there are so very few individual inquirers who engage in these studies; or at least partly on that ground?—Partly on that ground. Yes

2398. Do not you suppose that there are a very much larger number of individual inquirers of that kind on the continent of Europe than there are in England, that in France and Germany, at least, there are very many more individual inquirers of this kind?—You mean isolated inquirers not connected with laboratories or schools, as I understand you?

2399. Yes?—I have very little practical acquaintance with the continent except by means of periodicals; and of course it is not always stated where the inquiry is carried on. My idea from conversation, and so on, is that in Germany the number of individual inquirers is excessively small. I do not know of any results which have come out in that country during the last few years which have not been brought out in some physiological laboratory attached to some university or school.

2400. And do you think that the same is true of France?—I think so, because all the work which I have seen in French for the last 10 years has come entirely from the laboratories of Paris or Lyons.

2401. I understood you to say that inquiries in regular physiological schools abroad are conducted with much less regard for animal pain than they are in this country?—I beg your pardon, I made no observation at all about the conduct abroad.

2402. May I ask you whether you suppose they are so conducted?—I really do not know. I am entirely a home-bred physiologist and know very little practically of experiments abroad, except what I gather from periodicals.

2403. You know Béclard's book, and Claude Bernard's?—Yes; but I cannot speak on the practices of foreign physiologists with authority; I simply repeat what I hear; I have no personal knowledge.

2404. Have you no knowledge of Schiff's Inquiries?—I have knowledge of Schiff's Inquiries, but no special knowledge of the way in which he behaves and carries on his work in the laboratory. I cannot speak with any authority on that.

2405. With regard to the nature of the experiments which you have read about, would you not say that a great many of them were needless, and I will not say wanton, but experiments which you would be sorry to conduct yourself?—It is very difficult to say when an experiment is needless. One feels a difficulty in sitting in judgment upon one's fellow men in that way. It is quite possible. One knows that there have been needless experiments performed.

2406. Just to fix our ideas, take the case of excising the kidneys altogether from animals, and studying the results when the kidneys are excised, which is quoted here from Béclard's book. Should you think that an experiment which is not likely to be useful to scientific research?—I should think it most distinctly likely to produce useful scientific results as part and parcel of an investigation. I do not think there is any inquiry more promising than that of determining the place of production of urea, and in this inquiry the extirpation of the kidney is one important operation.

2407. Do you know Gavarret's Book on Heat produced by Living Creatures?—I know it cursorily; I looked at it some years ago.

2408. Do you suppose that experiments on baking animals to death are of the kind which would be conducted in English laboratories?—I should not like to say anything about it, unless I knew all the details of the experiment. Put in that form, I should say that "baking an animal to death" would not be useful.

2409. They were simply experiments to ascertain at what temperature the animal would survive?—It must depend so much upon what investigation the experiment was a part of, whether it was justifiable or not.

2410. Then your general impression is that a great many experiments conducted abroad are a class of experiments that you would be sorry to conduct yourself?—No, I would not go so far as that. So far as I know (and I only give this from hearsay, I speak this not as a physiologist, but simply as a person who has had things said to him,) the physiologists abroad are not so tender as I should be myself, or as are the English physiologists. I have no practical acquaintance with the physiological laboratories abroad in their working condition.

2411. I may take it that it is the intention, is it not, of this book, and of what I should call your school of thought, to introduce the general system of study abroad very much more generally into England than it has hitherto been introduced?—I think our study is a study entirely of our own; I mean, I think we teach physiology in a way that it is not taught on the continent at all.

2412. The experimental method is derived very much from the continent, is it not?—The experimental method is coeval with physiology.

Mr. J. Burdon-Sanderson, M.D., F.R.S., and Mr. M. Foster, M.D., F.R.S.

23 Oct. 1875.

2413. Quite so; but I understood you to say that hitherto it has been exceedingly little pursued in England, and not nearly enough?—I beg your pardon. I have made no statement in reference to that. I can only agree with what Dr. Sanderson has said, that, say, some 20 years ago, there was very little physiology carried on in England, and a great deal abroad. Experimental physiology and vivisection had been carried on in England before that time; and at one time, as for instance, if you take from the year 1810 to 1820, when Sir Charles Bell, and afterwards when Marshall Hall was working, probably nearly as much was being done in England then as on the continent at that particular time. Since then much more has been done on the continent and less in England.

2414. Still your object is to extend the experimental method in England, is it not?—My object is undoubtedly to advance physiological science, for which the experimental method is one good means.

2415. When your object has been attained, do you not think it is very possible that restraints may be desirable that are not now desirable simply because that method is not now much pursued?—I do not see any reason to think that, because the use of the method would be increased, therefore the good feeling which characterizes the Englishmen who have taken part in it would be different when they were many from what it is when they are few.

2416. Then you think there have been no abuses of any kind in the English schools?—I do not think there have been any.

2417. Now I understood you to say that for the purposes of demonstration you thought all experiments ought to be under anæsthetics?—All experiments causing pain.

2418. Did you mean by demonstration, demonstration in the larger classes of medicine, or demonstration in the laboratory?—I meant both.

2419. Are there not experiments in your own portion of this handbook which are, strictly speaking, demonstrative experiments, and which cannot be conducted under anæsthetics by any possibility? I will take two. One is an experiment which we were told by Professor Rolleston that you had never performed yourself, partly from horror of the pain,—that on recurrent sensibility. I do not know whether he was correct in that statement?—Quite so; I have not performed it, and have never seen it done; and I certainly should not offer that as a demonstration to students.

2420. Is it not the tendency of this book to suggest that as an experiment which the physiological teacher should show his students?—No, I think not; and if you read that chapter you will see that there is a very great difference in the manner in which that experiment is introduced as compared with others. In the majority of cases I have used the imperative; I have said "repeat" "devise," and "place," but on the question of recurrent sensibility I simply say, "This "is never witnessed in the frog. It can only be "shown in the higher animals," and I go on to describe a method which I took from Bernard, never having conducted it or seen it performed myself; and I put it in there simply because it does render complete that little section of physiology.

2421. Then the other experiment which I referred to (of course I am not sufficient physiologist to know how many there may be of that kind) was the experiment on raising the temperature of a healthy frog till it dies?—I beg your pardon, the healthy frog jumps out.

2422. No. I think that the description is that you put a net over to prevent it jumping out; that it is the object of this experiment, to raise the temperature of the water containing a frog secured by net-work?—Directly the frog becomes uneasy, one stops the experiment.

2423. But you have given no explanation of that at all in the book?—Perhaps I ought to have done so. I think you will say that there is nothing in it to lead you to suppose that you go on until the frog is dead. That is perfectly unnecessary. Directly the frog begins to move you have got the result of your experiment; you need not go on any further. The point is that the one frog is motionless, and that the other frog begins to move at a certain temperature. I put a gauze over it, so that you may have two or three repeated movements, that is all.

2424. I am very glad indeed to hear that explanation, because I think everybody would be mistaken as to the meaning of that part of the book?—Of course one has a great deal to think of in writing these directions, and in avoiding one difficulty one often falls into another.

The witnesses withdrew.

Adjourned to Monday next, at two o'clock.

Monday, 25th October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

Dr. JOHN ANTHONY, M.D., called in and examined.

Dr. J. Anthony, M.D.

25 Oct. 1875.

2425. (*Chairman.*) I think you were formerly a pupil of Sir Charles Bell?—I was during the period of his connexion with the Middlesex Hospital, to which I was attached.

2426. Were you selected by him among his pupils to fulfil the duties of dissector?—I was.

2427. Will you have the kindness to explain to the Commission what those duties were?—Sir Charles Bell's lectures being principally on the nervous system, or some of the functions arising from the distribution of the nerves, it was necessary that the dissections should be of a particularly neat and clean character. I was selected from 70 pupils for the purpose of performing those dissections, and having everything necessary in readiness for Sir Charles to lecture.

2428. At that time anæsthetics were not introduced?—No.

2429. Any experiment therefore which was in itself of a painful character must necessarily have inflicted its full amount of pain upon the animal experimented upon?—Quite so.

2430. Was Sir Charles Bell particularly careful in that respect?—I never saw him operate upon living animals; I prepared the subjects for his lectures on the nervous system; but at that time Sir Charles was not in the habit of giving lectures on vivisections; it was on demonstrations of his discoveries as to where the nerves were supplied in the dead subject.

2431. The cases in which you acted as dissector were not on the living animals?—Not on the living animals.

2432. Does it fall within your knowledge to speak at all as to Sir Charles' treatment of living animals?—I never saw it.

2433. Have you any means of saying whether he was very tender?—I can only speak from hearsay, from the statements of those who knew him well, that he was most kind and most feeling.

2434. That is to say, I presume, that he limited the infliction of pain within the narrowest limits possible?—So I understood.

2435. You were afterwards, I think, for a long time a student of physiology abroad?—At Paris.

2436. Speaking generally, have you any remarks to make about what you considered to be the tone of feeling on this subject there?—Among English or French do you mean?

2437. I mean generally in the lectures that you saw there, whoever were the people?—The English part of the class partook with myself of a degree of indignation at the cruelties which we saw manifested in the demonstration of the experiments on living creatures.

2438. How long ago was this?—In 1838.

2439. Looking to the published medical journals of the period, are you able to lay before the Commissioners from them, instances of what you consider to have been objectionable practices on this subject?—I have every reason to think that I can do so. My memory serves me, that the text books of the period were rather proud of giving the detail of these experiments; and therefore I think I can give a good résumé of such experiments.*

2440. So that if a certain time be allowed you, you think that you can substantiate from the published medical journals the statement which you have made generally about the state of things when you were at Paris?—Yes.

2441. Have you considered the subject which has been referred to us?—Very carefully.

2442. Do you consider that there is at this time a disposition to extend in this country the practice of vivisection?—I have every reason to think so.

2443. Do you think that it is desirable to take any measures on the part of the legislature here, to limit the treatment to which living animals may be exposed in this country?—That is a difficult question. Perhaps it would simplify matters if I were to read a short paper on which I have put down what I think would be advisable, and then your Lordship could put any question touching why I think so.

2444. If you please will you do that?—I think in the first place it is desirable that for the advantage of human beings, observations of the vital processes involving experiments on living creatures throughout the lower range of the animal kingdom, should be permitted. I take that as a postulate. Secondly, that such permission should be given in the form of a license to such persons only as have already shown great aptitude for the study of physiology, or the cognate sciences. Thirdly, that stringent regulations should be attached to such licenses, involving the giving of every facility for the inspection of the experiments by proper officials. Fourthly, that nothing in the nature of a public demonstration of vivisectional experiments of any kind should be permitted, such exhibition being perfectly useless on scientific grounds, very demoralising in its tendency, and only serving to minister to a morbid curiosity. I shall be very happy to say why I have formed such an opinion, as differing from the idea which I know now obtains with regard to the institution of laboratories.

2445. On the first point do you consider that observations of the vital processes, in involving experiments on living creatures, are absolutely necessary to the successful prosecution of physiology?—I think so. I think it is impossible that you could judge in the least, from the dead appearance of a nerve, what its functions would be. In fact when observations were made from those sources, persons arrived at the conclusion that all nerves were alike; a nerve was a nerve and very frequently for the relief of ticdoloreux, which is an exceedingly painful affection, before the days of Sir Charles Bell a section was made of a large nerve, which was observed to ramify over the face, and to the astonishment of the operator that did not relieve the pain the least in the world, but only took away the power of movement. In other words we know now that it was the nerve of motion. Nerves appear to be small thin white cords, some slightly redder than others; but we know now from experiments performed on living creatures that of these nerves, some are nerves of motion, some of sensation, and some of what we should call co-ordination. Others are nerves of special functions, just as the heart would beat day and night for three score years and ten; but if you stick it full of pins the individual's heart would not be conscious of it; the nerves that supply that, are nerves of special functions. If I take my microscope I merely recognise the nerves as very diminutive tubes filled with dead matter, looking almost like the coarse meat of sausages; and that is all we know about them in a dead form.

2446. You mention that to illustrate your first position, that it is desirable or necessary that observations of the vital processes, involving experiments on living creatures, should be permitted?—Yes; I named the lower range of the animal kingdom, that is to come as near our species as moral and religious grounds would permit.

2447. Now your next position is that such permission should be given in the form of a license to such persons only, as have already shown great aptitude for the study of physiology or the cognate sciences. You think that the persons qualified to turn such experiments to any real scientific use are a special class of persons?—Quite so; there would be no difficulty in identifying such persons in the profession, and I will name why I prefer the form of a license to giving any permission generally to attend at a laboratory. It would be probable for any man who was worth his salt, as a discoverer to be jealous; he would not allow for a single moment any person who might have access to that laboratory to witness what he was doing. If he were himself conscious of having the power of experimenting and so carrying it to great results, he would be most careful that those about him should not have an idea of what he was doing. Discoverers are jealous. Whatever discovery has taken place, it has never taken place by three or four men coming together and talking over something that has been done. It has been done in the quiet of a man's own atelier or work-room. I think the astronomer is best alone in his observatory, and that the microscopist best alone with his instrument. If three or four are gathered together, there is no work, it is mere talk, and there is no discovery.

2448. Then in your next proposition you say, that stringent regulations should be attached to such licenses. Would you kindly indicate to the Commission what is the nature of the regulations that you would propose?—I think that there, the greatest pains should be taken that the cruel element should be kept down as much as possible. What I saw in Paris (I do not know whether this is evidence or not) pointed to this, that very frequently men who are in the habit of making those experiments, at all events the French, are very careless of what becomes of the animal, when it has served its purpose. The brain is exposed, portions of it are cut, or pinched, or torn, and then the animal having served its purpose, is thrown on to the floor, to creep into the corner and die. I would give the license under such restrictions that everything approaching to cruelty should be prevented, and so that when it was possible, anasthetics should be given, either chloroform or ether, or the protoxide of azote, to negative the sensation when the experiment permitted of it. In other words, I would make it as merciful as I could.

2449. The object, as I understand, of the regulations

---

* Appendix III., § 3.

Dr. J. Anthony, M.D.

25 Oct. 1875.

would be to diminish the suffering of the animal; but are you prepared to give in detail any specification of regulations which, in your opinion, it would be judicious to attach to such licenses?—I have never considered that subject; I have merely proposed it in general terms. There would be no difficulty in filling up a sketch picture afterwards with the necessary detail.

2450. Fourthly you say, that nothing in the nature of a public demonstration of vivisectional experiments of any kind should be permitted, supposing that the creatures that are the subject of those experiments are so treated with a complete anœsthetic, as to be entirely insensible to pain, would you still adhere to that?—I would still adhere to that, I have thought that over very carefully; and I believe once you admit the principle that it may be allowed under certain circumstances, you would introduce the thin end of the wedge, it would be a matter of discussion about what was and what was not a legitimate object for exhibition. I believe that the more you keep the scenic element away the better. All that is done that is valuable to science is done in the quiet of a man's laboratory or room, as it may be, and then he communicates it to the body of the profession or physiologists in a proper manner, and it is so accepted. If that statement should be doubted, the experiment can be repeated by others, whose names would also carry weight, and then it comes before the profession in a proper manner. The reason of my stating that I would keep this matter as much as I possibly could from the public, is the existence of morbid curiosity. There is a morbid curiosity which is known to medical men well with reference to operations of all kinds. There are a certain number of persons who are very fond of coming to see the different operations at the hospitals. I look upon that, and particularly upon the desire of seeing these experiments on animals, as something very very morbid indeed. I may say I never gained one single fact by seeing these cruel experiments which I have seen in Paris. I know nothing more from them than I could have read in the current journals, or in the works of physiologists.

2451. We were told the other day by lecturers of great eminence, that in the first place demonstrations are never exhibited in this country except under complete anœsthesia, and secondly that the tone of feeling among the professors, and among the pupils also, there being two separate statements, the one regarding the professors, and the other regarding the pupils, was such that it would not be tolerated for a moment?—I am very glad to hear that.

2452. Now supposing that to be the tone of feeling and the anæsthesia to be complete, would you be afraid that a demoralization would follow if that practice were permitted to continue?—I think it a bad practice; I think it would be sensational instead of educational.

2453. Are there any other suggestions which you wish to offer to the commission?—There is one point that you have not referred to, on which I would say a word, namely, that it should be one of the conditions of the licenses that the atelier or workshop or place should be open at all times, that every facility should be given for inspection by proper officials, I mean by that, inspection by those persons who would not care in the least what the functions of the nerves or other parts of the body might be, but would simply take care that the thing should be carried on in conformity with regulations laid down. There would be no difficulty I think in carrying that out, and no jealousy caused by it.

2454. But supposing one of these jealous discoverers of whom you have spoken to be engaged in a series of complicated experiments, do you think it would be possible to have an inspector put over him, so that the two objects could be combined, the efficiency of the inspection, and the successful prosecution of the experiment?—I think so; because the inspector having access at all times to the place where these experiments were being carried on, if a man of intelligence, would have no difficulty in arriving at a conclusion whether the license was acting in conformity with the regulations. Public opinion would soon bring that right. I merely wish to prove that instead of (as has been proposed I believe), having ateliers or galleries to which the public should be admitted; that is taking it that publicity would be the best safeguard against cruelty, I think that this arrangement would entail practically, that no man who was making a series of careful experiments, would care to go to a place and make those experiments with a parcel of people chattering in a gallery round him, or persons looking on.

2455. But on the other hand you are not afraid that with such a proposal as your own, one of two things might happen, either that the inspection would be perfunctory, and the real severity inflicted at same times when the inspector was not likely to come, or that if it were really efficient, the jealousy of the experiments would operate as a difficulty in the way of accomplishing the scientific results desired?—I see where the difficulty would lie, and I guard against it, so far as I possibly can. In the first instance, I would not grant a license to any man except he was, in the general opinion, I may say, of the members of the profession, a fit and proper person to carry on those experiments; and then I think that if you must have safeguards, considering that the man if he is to be licensed, has got work to do, that work would be better done, and the cruelty would be guarded against better, by inspection by a proper official, who might come at any period during the experiments, than it would be by having simply a number of the public present in a gallery who knew nothing of the regulations and nothing of the experiment, excepting that pain was inflicted. Pain there must be in the majority of experiments where the animal cannot be subjected to an anæsthetic agent.

2456. Are you of opinion that in the whole number of necessary or desirable experiments by far the greater portion can be performed under anæsthetics?—Many can be; but nothing, I believe, with regard to the experiments on the nerves of the body. If you wish to arrive at a satisfactory conclusion the less elements you have which would confuse you the better. If the animal is placed under the influence of an anæsthetic, which acts directly through the nerves, it is impossible to arrive at a satisfactory conclusion as to what, in a normal condition, that nerve is when in the fulfilment of its full functions.

2457. But we have had a good deal of evidence to lead us to believe, that of the whole number of experiments on living animals, which are to be considered as either necessary or desirable, a very large proportion may be performed under complete anæsthesia?—I think it may be so; I have no reason to suppose the contrary. If, for example, a man wishes to investigate inflammation in any particular part, he can see the effect of the inflammation just as well whether the animal is conscious that he is cutting that part or not, so far as the blood is concerned; but with regard to all the experiments on the nervous system, I think it is impossible to arrive at a satisfactory conclusion when the animal is not conscious of pain.

2458. Then we have understood also that of the experiments where there must necessarily, if they are performed at all, be a consciousness of pain, it often happens that the larger portion of the pain may be entirely removed by anæsthetics, and that the smaller portion only will remain in which the animal must necessarily be conscious. Do you agree with that?—I think it may be taken to be so.

2459. Then upon the whole, you are of opinion, that the pain to which animals ought to be subjected for the prosecution of science is limited to a very small portion of the whole number of experiments?—So far as we have gone hitherto; but I think we are merely on the threshold. I believe that much more will be done in this part of the 19th century than ever has been done in the investigation of what are termed vital functions. May I venture one observation on that? It is this, that it is impossible to deny the evidence that the animals of the lower range do not feel pain as we

Dr. J. Anthony, M.D.

25 Oct. 1875.

feel pain. I should be sorry to give the impression abroad any sort of bias on my part towards experimenting on animals; for I could not do it. My reason tells me, however, that experimenting on these inferior creatures of a lower order, is the only way we have of arriving at satisfactory conclusions in many very important problems; but I do not think that the cab horse, for instance, when it is whipped, feels exactly as we feel. It is not the case, as Shakespeare says, that "The beetle that we tread upon feels a pang "as great as when a giant dies;" we know that is not correct now. The lower you go down in the scale of animated nature, the less you find of what we call nervous sensation. The lower animals have the nerves of special functions, for the beating of the heart and the inflation of the lungs for example; but if these creatures receive a cut or a blow, I do not think that they would feel it as the higher animal would do.

2460. (*Lord Winmarleigh.*) With regard to that last answer, what are the proofs of that which have been made public?—I do not know whether you are aware that a Dr. Badham, who went into that subject, wrote a small book on it; he was an Oxford man and a travelling professor, and he made it his particular business to collect evidence, and himself to go into experiments on that subject; and he went as high up as he possibly could to get evidence; but he also went low down among the articulata. Certain animals, you know, have the power of throwing their own limbs off, as crabs and lobsters. Experiments of that nature have been made with flies; the fly is so fond of sugar and water that you can cut the extremities of a fly's legs off and the creature will go on sucking although the extremities of all its legs are cut off. This fact has been shown in museums again and again. Taking the predations beetles, the carnivora, a pin has been stuck through them and they have been thought to be dead and have revived, and have drawn the pin away, and walked off to a neighbour, and eaten it.

2461. Is that a proof that none of the inferior animals suffer pain in the same way as the higher ones?—My point is that none of the inferior animals suffer in the same degree what we should call the sensation of pain. The nervous system in them is a system of what we should call the nerves of organic life to carry on the breathing and locomotion; and I presume that if an animal finds anything annoys it, it has modes of expressing its disapprobation. But mammals have the same nerves of organic life, with a brain superadded; and hence their sensation of pain is very different.

2462. Have those proofs been so far established that that they are recognised by physiologists as indisputable?—I think I may say so. I do not think that what I am now telling you is mere matter of opinion, it is looked upon as matter of fact.

2463. At the same time is it not the fact that animals, when they are subjected to certain modes of punishment, do exhibit a sense of very great torture; I will take for instance a dog?—That is a mammal. I was speaking now principally of the lower animals; when you get down to the articulata, the coleoptera, and the neuroptera, in fact insects in the lower range of animals.

2464. The horse of which you were speaking just now, is a mammal also?—Yes, but it belongs to a lower species than we do. We belong to the very highest species in the range, and I believe that by taking a descending scale, the lower you go down, starting from the highest mammal down to the lowest, you will find a gradual absence of what we should call ordinary nervous sensation.

2465. But seeing that a horse under certain operations groans in a dreadful manner, is not that a proof that it is suffering pain?—I would not for a single moment say that the animal does not suffer, and suffer acutely. I am afraid that what I am now saying may open possibly a door for those who would wish to carry on experiments, cruelty or no cruelty, but what I say is that those lower orders of the creation that are still furnished with a large number of nerves, are furnished principally with the nerves for carrying on organic life. You may pull their limbs off, and they seem to manifest no particular disapprobation. It must be familiar to all that if you put your finger on a daddy long legs, as it is called, the animal will fly off, leaving one of its limbs behind, but he does not seem to suffer from that.

2466. But are there not parts of the daddy long legs that are affected with great pain?—I think not. I have no reason to think that there is any particular pain that can be felt by it. We have reason to think that with regard to the creatures that seem to be required in very enormous number for food for others, it is a merciful arrangement that they should not feel the pain; that they live on in happiness till the day of their destiny comes.

2467. Have you ever paid attention to the comparison between the discoveries made by the French physiologists, and those made by the English physiologists?—Yes, I may say I have.

2468. Which should you say have have contributed most to the service of physiology, the French or the English?—I say that nothing that the French have ever done bears, for a single moment, any comparison with the discoveries of Sir Charles Bell. I happened to be a pupil at a period when Sir Charles Bell and Herbert Mayo were the English physiologists, and Magendie was their rival in France.

2469. So that you think that the English system, where there is less cruelty, has been equally beneficial to physiology with the French?—I think infinitely superior.

2470. You stated that you thought no person should have a license to practice experiments in physiology unless he was known to have qualifications for it?—My reason for stating that is that it would take out to a certain extent the element of mere curiosity.

2471. But supposing that the student of physiology was not of the medical profession, what means would he have of showing his qualifications?—I think he would be certainly known to some persons of note as a physiologist, or he would place himself very rapidly in connexion with some one of the kind. If you were accustomed either to the use of the microscope or to experiments in any of the cognate sciences you would know that the first thing a man does when he gets such proclivities is to place himself in communication, through some mutual friend, with men high in the profession who have also followed the subject out. He must first find out what others have done, and get some one to put him in the way. If he has got a *furore* for carrying on experiments, advice will be given to him as to the best mode of conducting them; that is, providing it is not mere curiosity, something merely in the amateur way.

2472. Some authority, the Secretary of State, or some other public authority, must be charged with the duty of giving such licenses?—Yes.

2473. How would you enable him to test the qualification of the person wanting a license; for instance, the Secretary of State?—Supposing we take any medical school, King's College, or University College, among the number of 60 or 70 pupils, it would be very soon known to the professors that there was one particular young man who had shown a particular talent for the investigation of these subjects; he is constantly about and asking questions; he shows by his questions that he has got something more in his brain than the ordinary run of students; there would be no difficulty then in the professors joining to recommend to the Secretary of State that such a young man should be under certain regulations, given a licence to carry out the experiments which he evidently was fond of.

2474. What is the nature of the restrictions that you would insert into a licence granted by the Secretary of State, or others?—I have not considered that sufficiently, and it would be a matter for very grave consideration. You should surround the licence with such restrictions as would make the element of cruelty (which must subsist to a certain extent) as small as possible. I can see no difficulty in imagining that a licence would be granted with certain restrictions, not too many. I would make a general blocking out of my sketch before I filled in the details.

2475. In fact you think that there would be no difficulty about it?—I think there would be no difficulty.

2476. (*Mr. Forster.*) You draw a line as regards pain between man and other mammals. Do you think that there is much difference amongst these other mammals as to their sensibility to pain?—It would only be a matter of opinion. I should not be able to prove the difference between the man and the animal, they come so near together.

2477. My question was rather as to the difference amongst other mammals?—We only get it from analogy. As you go lower down from the very highest organization of the nervous system, pain ceases to be felt in the lower as it would be felt in the higher. It is a matter of degree; I think it is in proportion; with a brain weighing 3 lbs. to 4 lbs. the individual would feel pain very differently from what he would if it weighed only a few ounces.

2478. Would not dogs be as likely to suffer pain as any other animals?—Of course if you take the canine race, the dog, the cat, or any animals of that developmant of brain, I think they would all suffer alike; but I do not think that they would suffer as men suffer.

2479. But would they not be as likely to suffer pain as any animals, except man?—Yes.

2480. Why is it that dogs and cats are more taken than other animals for experiments?—They are more easily got at, and are cheaper.

2481. Is there no reason connected with the experiment itself which makes it desirable to get them for the purpose?—No, excepting that they are as high up in the mammals as could be got at a cheap rate. A sheep would be a very dear animal to perform an experiment upon. I believe Sir Charles Bell's experiments were made chiefly on a donkey.

2482. But I suppose there are some experiments which would be useless; unless they were made on animals as nearly approaching man as possible?—Yes; I think you may say it would certainly be unsatisfactory if it were brought before the profession that certain functions were judged of by a function in an inferior organization.

2483. Now I suppose you would consider that it is probable that a frog suffers less pain than a dog?—Certainly.

2484. Why is it that in some experiments that they take frogs, and in others dogs?—Because in the frog the nervous system, such as it is, is very large in proportion to the rest; and also Galvani in his experiments, having accidentally observed in touching the nerve of a frog, prepared for culinary purposes, with metals producing a galvanic current, that the limb was violently agitated, it was found that the nerves were very susceptible; but it does not follow that because the nerves were susceptible to movement, sensation should be equal. It was a great discovery of Sir Charles Bell, that the nerves of the body arising from the spine were half of them merely nerves of sensation, and the other half of them nerves of motion. The motion might be vigorous though the sensation leading to that motion might not be what we should call our sensation, a sensation of pain,—will you allow me to give as an illustration of what I have been saying about the difference of the nerves, this fact? I was saying that the nerves of motion did not depend upon sensation. Now, when a horse goes to the knackers of course he is killed, and they cut his head off. Before the knacker however begins to remove the skin of that horse, he passes a a long rod down the spinal marrow. Why? Because if he begins to skin that horse without doing that, although we cannot believe that there is any sensation, yet for an hour or an hour and a half there would be sufficient irritability in the nerves, for that horse to kick and perhaps break the man's arm, although as I say the head has been cut off for some time.

2485. You stated that you would not allow any vivisectional experiments for the purpose of demonstration. We have had some witnesses who have said that they consider that students either of medicine or surgery cannot properly be taught their profession unless they see such experiments; is that your view?—I do not think so. I think a man can understand that a medicine is a purgative, though he has not seen an operation to prove it.

2486. We had this case put before us, that it is sometimes very desirable for a practitioner to know whether a patient really has had strychnine or not, and that it would be very difficult for him to know what the effects of strychnine was, unless he either saw it in a human being (and he might not have had that opportunity) or had actually seen it in some animal; and that was given to us at some reason for the desirability of seeing an animal under strychnine?—That does not shake my opinion, because the effects of strychnine on the body are such that they are phenomena of the coarsest nature. The particular spasm induced by strychnine is such that it would be impossible for a single moment to mistake those phenomena as phenomena arising from any other other source.

2487. Then as regards merely the acquisition of such knowledge it is asserted that it is necessary for them to see the experiments in order to be good practitioners. We are told that even in such a matter as the circulation of the blood they obtain the knowledge of that by seeing it in a perfectly different way from what they do by hearing of it?—I think that that would hold true of everything throughout life. What you have seen fixes itself better on the memory; but is it necessary to go through the experiment of cutting open the chest of a frog, being at the same time particular not to kill it; and then to turn its lungs out, in order to see the circulation of the blood? Fond as I am of physiology I would not do that for the world.

2488. You have had considerable experience in the medical profession?—I have.

2489. Do you think that a man who had seen the circulation of the blood in a living animal would to any extent worth taking much account of, be likely to make a better surgeon or physician than a man who had not?—Not the least, he could merely see the circulation of the blood in the web of a frog's blood, or in a fish's gill, or in some of the very inferior animals; but we are not at all sure that the circulation of the blood in them is conducted in the same mode that ours is; they do not breathe by lungs but by pouches; a different arrangement altogether.

2490. (*Sir John Karslake.*) From what I gather, you do not practice vivisection yourself at all?—I am continually occupied in dissecting with the microscope.

2491. But not in making experiments on living animals?—No, not on living animals.

2492. Might I ask you this question, have you ever seen a dog, for instance, or any animal, under the influence of strychnine?—Yes. I have poisoned a very favourite dog myself with it.

2493. Intentionally administered you mean?—Yes.

2494. I rather gather also that it has not been any part of your duty to lecture to classes of pupils?—Not on this subject.

2495. Would you think that those who have for many years past had pupils under their charge, would be better able to form an opinion as to the value of demonstration than those who have not?—I can scarcely answer the question, because it is an opinion as to whether another person might be capable of forming an opinion.

2496. Now with reference to the license that you propose, it seems to me to be very much a question of detail, can you give us any detail; have you formed any opinion yourself as to the character of the details connected with such a license?—Yes, I have asked myself the question, what I should require, or what I would do myself. Take a case; supposing I wished to follow out experiments on the nerve which supplies sensation to the face; then I should begin to think among the lower animals, which could be got at at a

Dr. J. Anthony, M.D.

25 Oct. 1875.

moderate price that I could act upon; then I should begin to think whether I should require any one to assist me, either in the way of holding the animal, or in the way of performing some of the inferior parts of the experiment; then what place would be convenient for performing it; naturally the cries of the animal submitted to experiment would, as it is termed, raise the neighbourhood; you would be obliged to consider whether you had got facilities for the purpose at the place where you lodged or lived, or any outhouse connected with it. That suggested itself to my mind; therefore an individual making such experiments, that is to say, getting a license to make such experiments; would have in his own particular capacity to make a series of arrangements for carrying them out. I would allow him to make those arrangements, and not let the arrangements be made for him in the form of a particular laboratory. You might grant him the use of a room at a particular place, but he should have that room to himself, and not be subjected to be interrupted by any one except the official who came in from time to time to see that matters had been, what is called, decently conducted.

2497. Have you formed any opinion of what would be the function of that person who is to come from time to time, and inspect the operations which are going on?—Yes, I think that an intelligent person who was properly informed, would know it when cruelty was manifested, it would be made afterwards matter of conversation among the professors; I believe that the man would not stand alone who was making these experiments; he would from time to time say that he was getting on well, and hoped to be able in a short time to bring something forward that would be of value. Supposing that the official was a man properly informed I think he would be enabled to judge whether an undue amount of cruelty was being made use of.

2498. Might I ask, is the inspector, according to your view, to be an educated physiologist himself?—No; I think he would naturally be a member of the medical profession, but not connected in any way himself with experimenting. I think a man would be very jealous of any person coming into any room where he was at work on experiments, who might be engaged, or quasi engaged in the same work with himself; he might take the wind out of the sails of the other; see what he was doing, and then go and perhaps obtain priority of publication.

2499. Then he is to be a medical man, but not a skilled physiologist, as I understand you?—Not a skilled physiologist.

2500. As far as I understand it, you go to this extent, that a license is to be granted, on the recommendation of somebody, to carry on an experiment in some particular place, subject to the inspection of a person who is not a skilled physiologist, but who has sufficient skill to know whether that experiment is cruel or not?—Yes.

2501. Are there any other details which you have in your mind?—I think if you had a place furnished with certain appliances, made convenient for a student of physiology, he might be assigned, as the French say, a cabinet, of which the individual should have himself the key, and he should be enabled to ask anyone else to come and assist him in that particular cabinet; but that he should not have to go to a public laboratory to which anyone could have access, and in which every person who wished could see what he was doing from the gallery.

2502. Your view is that the license should exclude everybody from his laboratory except what may be called an assistant?—Yes.

2503. And that no one should be allowed to see the experiment going on except the official?—Yes; and that the official, as people in common language would express it, should be the person to see fair play.

2504. Are there any other details which occur to you in the license which you would propose?—No, I think not.

2505. Have you considered at all what the consequences would be of a person who is an eminent physiologist doing that which the unskilled inspector considers to be cruel?—That is going into a series of possibilities that one has scarcely contemplated. Of course one knows that such things must be, but they are generally provided for by those who are more skilled in seeing how you should provide for them than I am. If it were noised abroad that Mr. A.B. was a cruel wretch, I think there would be no difficulty in bringing him before the tribunal of public opinion.

2506. But supposing the physiologist is a very eminent man, and the inspector a man of no skill at all compared to the eminent physiologist, and he were to say, "I have seen an experiment to-day performed by Dr. so and so which inflicted great pain," do not you think that the profession would give credit to Dr. so and so rather than to the inspector?—Yes, I think if he were a man of weight, he would be able to justify himself.

2507. But you would not grant the license to a man who was not a man of weight, as I understood you?—No, I did not say that. I said a man who showed a peculiar aptitude for the study of physiology. For instance, he has got a degree, we will suppose, but still he is a young physiologist; he has got young blood, and young brains, and he devotes himself to physiology. He might be a cruel creature, and that would soon be found out, and he would be made amenable to public opinion. In fact the very fact of his having done anything cruel would vitiate his license; because I take it that the license would only be granted from year to year. I would make the license annual, or for some definite period.

2508. (*Lord Winmarleigh.*) Would you apply that to the heads of the school?—They would submit to it for the known good that would arise out of it in the other case.

2509. (*Sir John Karslake.*) Do you know of any instances yourself of young men, from mere curiosity, carrying on these experiments?—Yes.

2510. Can you mention them?—No, I am prepared to say that I could mention them, but I should scarcely like to do so.

2511. I want to know whether there are instances under your own knowledge at the present moment of persons, from mere idle curiosity, with no sufficient reason at all, carrying out these experiments?—I am afraid there are.

2512. You cannot give instances?—No.

2513. Where do they exist, in London or the provinces?—In the provinces. Of late years all my experience has been in the provinces. Of course I have juveniles coming forward to ask me sometimes with regard to various points of physiology, and they tell me candidly what they are doing, and I am obliged to shake my head occasionally.

2514. Are these young medical practitioners?—Yes.

2515. Who, in your judgment, are engaged in vivisection without any justifiable object, and merely from curiosity?—Merely from curiosity.

2516. How long has that state of things been in existence, in your opinion?—A number of years.

2517. I ask you that question not as an opinion which you have formed of a thing that may be, but of a thing that exists?—Yes; guinea pigs seem to be the creatures that are the greatest favourites for being operated upon by those who do not wish to go to great expense, and kittens, and cats, and stray dogs, now and then.

2518. In these cases are anæsthetics used in your opinion?—No; or if an anæsthetic is used it is only to watch the effect of an anæsthetic; but an anæsthetic is not used to diminish the pain of the creature; the man using it would be one who wished to try the effect of what that anæsthetic would do.

2519. But you are really of opinion that there are persons who carry on these experiments, and who do not use anæsthetics, unless it is convenient for them to do so?—Yes; I think it is not from want of feeling, but they do not think about it. They want to know

Dr. J. Anthony, M.D.

25 Oct. 1875.

something, and the creature is utilised for that particular purpose.

2520. And you cannot tell us more specifically where, in your opinion, this state of things exists?—No.

2521. Is it done in private houses?—Yes.

2522. And are several of them present at the same time?—Yes.

2523. And they do not feel among them any shame in performing these operations?—Not the least.

2524. Having stated that, do you say you cannot give us any further clue, so that further inquiries might be made?—I am afraid I must refuse it, on the ground that it is knowledge I have come at, and which was given to me guilelessly without any idea of harm. I could not drag down public opinion on friends or acquaintances who have informed me that they have done certain things of this sort.

2525. But do you think that your shaking your head as you say, has had any effect upon them?—Yes, because I have gone further; I have told them very candidly what I thought about the matter, and I think strongly about it; and I think it has had an effect. When a man gets at all enthusiastic over matters he is very apt to disregard a mere "jo-bation" as he would call it.

2526. As I understand it, you cannot give us any further clue, or any clue at all in fact, as to where these practices exist?—No, merely that I have the consciousness that the thing is done, has been done, and probably will be done.

2527. And that is in the provinces, and not in London? — My knowledge does not extend to London.

2528. (*Lord Winmarleigh.*) Does that which you have been speaking of prevail to any great extent?—No, merely on the part of a few enthusiastic students.

2529. (*Mr. Huxley.*) Will you be so kind as to tell us what is the nature of the experiments to which you refer?—Experiments principally on the subjects connected with parturition, and also with regard to the circulation of the blood, and the effects of inflammation. If you take a frog's lung, and put a drop of acetic acid upon it, or make a scratch with a fine needle, in a few minutes you will find the effect of what would end in inflammation when it occurs in a higher being. It is very interesting and instructive to look at, but it is cruel to the frog.

2530. If then a person were to fasten up a frog's foot in the ordinary way for the purpose of seeing the circulation, which is an operation which gives no pain, and if that person were to put a little drop of acetic acid, or to make a scratch with a pin so as to see those very wondrous phenomena of congestion, (which probably few persons can imagine unless they have seen them,) if, I say, a medical man does that for the purpose of understanding better than he understood before the nature of the process of inflammation, do you consider that a barbarity which should be put down?—Certainly not; I have done it myself often enough.

2531. But that is one of the experiments which you have mentioned. I gather from you now that you do not consider that a case worthy of being put down by legislature?—Not if you confine yourself to merely watching the circulation of the blood in the gills of certain fishes, or in the web of a frog's foot. The frog can be put under chloroform if you like, and the circulation goes on just as well if you subject the frog to chlorofrom, giving him a small portion of the air to breathe. You use chloroform not to remove pain, because I believe the creature does not suffer pain from a mere scratch of a fine needle, but that he should not, as he would naturally and instinctively do, pull his toes away. You do not want to destroy the sensation of pain, but it is simply that then he loses a portion of the irritability, and he does not instinctively draw the part away.

2532. I wish to get back to our previous position. You stated to Sir John Karslake, that within your own knowledge medical practitioners in the country were in the habit of performing experiments which you considered cruel and unnecessary?—Yes, they have come to my knowledge.

2533. You were kind enough, in reply to my question as to the nature of those experiments, to mention the nature of those experiments, and among them you stated that the watching of the development of the inflammation of a frog's foot was one?—That would not be part of the cruelty, the watching of the circulation or the effect of inflammation on a frog's foot. I named the cutting open a frog, and turning the lungs outside, and being very careful at the same time not to kill the animal, and watching the inflammation when the lungs are outside. There was the cruelty. It was not the watching the inflammation, or the scratch with the needle, that produced the inflammation of which I spoke; it was preparatory to that. You are very carefully directed in certain books on these subjects, how you are to cut the creature in such a way as that you will get the lungs entirely external, and not kill the animal.

2534. In such books as I am acquainted with, it is stated that that experiment may be performed after the frog has been pithed or its brain destroyed, and as every experimentor knows, it is more convenient to have that done?—Yes.

2535. In the cases to which you refer was nothing of that kind done?—Nothing of that kind was done.

2536. But such experiments as those which you have mentioned are those to which you have referred as being the experiments which need legislative interference?—They would merely come in as part of what I have heard. Mind I have not seen anything of the sort. I would not see it. No sum would tempt me to go and see these things performed.

2537. Will you be so good as to tell the Commission what is the severest kind of experiment amongst those to which you refer, so that we may have the extremest case clearly before us?—Mind, I can only go upon hearsay. I would name the experiment on the generative parts of guinea pigs, on the fallopian tubes, portions of the uterus impregnated and unimpregnated.

2538. For the purpose of repeating Bischoff's experiment, do you mean?—Yes, probably.

2539. The experiment consists in tying one fallopian tube and leaving the other, does it not?—Yes.

2540. Have you ever seen that experiment done?—Never.

2541. You therefore cannot tell the Commission how long the operation lasts?—No; since my studies in Paris I have most carefully avoided seeing anything of the kind.

2542. You cannot give the Commission any idea of how long the operation lasts, or within what period of time after the operation a guinea pig that has undergone it is in its usual condition?—No, I know nothing of it. If I heard that such a thing was going on in the next room, I should walk out.

2543. You have no personal knowledge of it in fact?—No, but I believe that such things are done, from conversations which I have held.

2544. And the case which you have just put before us is the worst?—I have never heard of anything worse.

2545. (*Sir John Karslake.*) Might that operation be performed under chloroform?—Yes.

2546. (*Mr. Forster.*) Although you have never witnessed the operation, and would refuse to do so, have you an opinion whether it would inflict much pain?—The mere tying of the fallopian tube would probably give no pain. A physiologist would know that the interior of all animals is not gifted with nerves of sensation. It would be in the cutting through of the skin that there would inevitably be pain. There would be the painful part. The painful part would not be in the physiological experiment of trying the fallopian tube; it would be in cutting through the skin to get at the fallopian tube.

2547. (*Mr. Huxley.*) You are doubtless familiar

Dr. J. Anthony, M.D.

25 Oct. 1875.

with the fact that the operation called "spaying" is largely performed on sows?—Yes, I have seen it.

2548. Would you state whether the experiment which you have just referred to would inflict one whit more pain than that operation of spaying, or as much pain?—No, it would not inflict nearly so much.

2549. So that an operation which is constantly performed on sows, in order to get them to fatten a little faster, is an operation decidedly more painful than that which you say is carried on for scientific purposes?—Yes.

2550. I should like to ask you a few questions about a statement which you have made; not because I differ from you, but for the purpose of bringing out the grounds of your statement. You stated that in your belief the animals of lower organization than ourselves in all probability suffer less pain than we do?—Yes.

2551. I think it might be said that that conviction in the minds of physiologists arises, I may say, from some four grounds; that is to say, that when we suffer pain from any operation or injury, there is in the first place a very large amount of the pain which arises from what I may call the hyper-æsthesia of civilisation?—Yes.

2552. You are doubtless familiar, as every physiologist is, with the fact that one of the most painful events in the life of a woman, parturition, which to civilised women living under ordinary conditions of life involves long hours of agony, is got through by savage women without any inconvenience; that in fact, a savage woman will often get up and carry a burden within an hour after it?—I have seen that myself abroad.

2553. I have asked you whether the conditions of civilisation in the first place do not give rise to a great deal of what we feel of pain; and I understand that that is your opinion about it?—Yes; but supposing you take it not in the adult but in the child, you can have no moral consideration connected with it. I do not know whether you would consider that a series of generations might have acquired a greater amount of delicacy in organisations, so that both adult and child would participate in it.

2554. That it another consideration. Then there is another source of pain which is very important in the case of human beings, viz., anticipation?—Yes.

2555. Then thirdly, there is a very great source of pain following upon injuries in the human subject, and in the civilized human subject especially, which is what you know familiarly enough as constitutional irritation?—Yes.

2556. That, you will bear me out, does not prevail in animals as it does in the human subject?—That is so.

2557. And then there is a fourth element in pain, what we may call necessary pain, that which must under all circumstances follow?—Yes.

2558. Then there comes another great difficulty about judging of pain in animals, and I am particularly anxious that the Commission should hear from you, as one having very strong humanitarian views, what is the true condition of that question. One of the great signs of pain is struggling or crying, is it not?—Yes; and you are aware, better than I am, that as in the case of what happens in the case of the knacker and the horse to which I have alluded, struggling does not always signify pain.

2559. Taking the case you mentioned just now, you have in the horse all the signs that we commonly have of violent pain, when it is as morally certain as anything can be, that the animal is insensible to that pain?—Certainly.

2560. I am particularly glad to get this from you, because only two or three days ago we had brought before us a charge of cruelty against a teacher of having shown that which was cruel to a class of young girls. It was based on this statement, that the teacher had bought in a shop a lobster, which she believed to be dead, and had brought it to this class; and the allegation was that she cut the lobster to pieces, (it turned out when the matter was sifted, that that simply meant that she cut it,) and then, under those circumstances, the lobster moved. Now let me ask you, was that even the shadow of evidence that the lobster had any sensation?—No.

2561. I understood you to say just now, that you thought that Sir Charles Bell's discoveries had been of vastly greater importance than anything that has been done in France?—I think so.

2562. I do not wish to dispute your opinion; but may I ask if you have been familiar with Claude Bernard's researches of late years?—Yes, I know them generally; but I take it that the discovery of Sir Charles Bell with regard to the nerves arising from the spinal cord takes precedence over everything.

2563. Then you spoke of the jealousy of experimenters towards one another. I daresay that there is such a feeling, and no doubt it does obtain to a certain extent, but I do not think that it obtains quite to the extent that you suppose; and my reason for saying so is this; I do not know whether you are aware of the organisation of physiological research in Germany?—I do not know how far I can claim such knowledge; I have lived in Germany some time.

2564. You know Ludwig's name very well, no doubt?—Yes.

2565. You are aware that at Leipzig Ludwig has the finest physiological laboratory in the world?—Yes.

2566. And that for many years past there have been carried out in that laboratory, really under Ludwig's superintendence, a great series of most important researches, which researches are carried on by persons trained by him. Those persons have all the credit of the researches, and Ludwig has never shown the slightest jealousy of those persons?—Would you not rather say that that was the exception rather than the rule?

2567. I think that the same thing is going on in France at the present time. Claude Bernard has had many distinguished pupils; Müller of Berlin had many distinguished pupils; and Pflüger of Bonn has had many distinguished pupils; and the experience of the last 20 years has been that experimenters have tried by all means to get persons to work in their laboratories?—No doubt. But where a man wished to follow out a particular course of experimentation himself, do you not think that he would do that in what the French would call a cabinet particulier?

2568. No doubt if Ludwig wishes to follow out a particular research he does it in his own room, but that does not prevent others from making researches in the laboratory under him, does it?—I would ask whether you think that such discoveries as Sir Charles Bell made would be best got at in a public laboratory?

2569. I will put it in this way; do you see any objection to a public laboratory, supposing that the persons who got there have their own private rooms?—None; because that would bring it under the conditions which I named, viz., that it should be an essentially private room provided with conveniences.

2570. But I apprehend that the proposal made here, that there should be public laboratories at which research should be carried on, means laboratories under something like those conditions?—I thought not. I thought it meant laboratories where there would be a sort of gallery where the public would see what was done, and I say that because that was named to me in correspondence; and it was to point out the objection applying to that that I named the matter.

2571. I observed that when speaking of public surgical operations, you mentioned that there are some persons who go there as persons go to see a hanging, because they like to see it, and no doubt that is very condemnable; but do you think that that fact is any valid reason against permitting public operations?—No. It is like people getting up a party of pleasure to go to a battle for the purpose of seeing it.

2572. We all know that in the theatres attached to surgical hospitals the persons who are in those theatres while operations are going on are serious students of medicine; and I presume, although there may be in a a large number some three or four persons of morbid curiosity, yet you would not for a moment say that that is the case with regard to the vast majority of persons who attend those operations?—No, certainly not.

2573. So that that fact would constitute no argument against permitting public operations?—No; on the contrary, I have recommended certain persons to go and witness these operations; for instance, young clergymen, because I think that they may be placed under conditions in which it will be necessary for them to be able to stand the sight of blood. Books are written and lectures are given to enable a young clergyman to meet the emergency of some particular thing which might happen in his own place where he might be present; and if he was a poor creature who had never seen blood flowing, he might faint as much as the sufferer.

2574. I daresay it is within your experience that to a young student beginning his career there is something inexpressibly shocking in seeing a dead man laid out on a table?—Fearful.

2575. But by degrees a medical man becomes used to it, and undoubtedly does not think so much of it as other people?—One of the arguments against the profession being jurors is that they are too much accustomed to it; that they are hardened.

2576. But although that hardening is very necessary for them, do I understand you to think that it makes the men who are so hardened in relation to that particular matter one whit less humane or less tender-hearted in all other relations?—No, I do not think it does.

2577. You doubtless have a very extensive knowledge of the medical profession, and would you say of the medical profession that they are hard hearted and careless of cruelty?—No, on the contrary every day of the week they show that they have kind feelings by doing kind acts without being paid for them.

2578. Then to apply all that to the subject before us, why is it so certain that persons who pursue physiology in the same sense as a surgeon pursues surgery, must be hard hearted if they are witnessing operations not a whit more shocking than surgeons see in the operating theatre?—Well, I take it that they get the same sort of feeling as the woman is said to have who skins eels—she is so accustomed to it that she cannot realise in the least that the eels feel anything—it is part of her business. And I think that the continual sight of animals being acted upon, particularly if the observer feels any enthusiasm for the pursuit, in a very short time blinds the man's sense of humanity.

2579. I understand you to say by that, that he becomes blunter in regard to the inflictions of that particular kind of pain?—Yes.

2580. And we agreed just now that though the surgeon becomes blunter with regard to the particular kind of pain which he sees in the theatre, yet it makes him none the worse man in other relations?—Yes.

2581. And in the same way a person who is continually making experiments on animals is not so qualmish in regard to that subject as other people are?—He would think very little of cutting off the top of the skull of the next pigeon or kitten he might get, in order to satisfy a simple curiosity, a thing that another man would not do.

2582. Now do you base that conclusion on simple reasoning or on experience; because, if I may venture to say so, it in no way accords with my experience?—I have carefully avoided seeing experiments in vivisection after the awful dose which I had of it in Paris in 1838. The men there seemed to care no more for the pain of the creature being operated upon than if it were so much inorganic matter.

2583. And how far, may I ask, do you think that that arises from the peculiarities of the character of the nation, and how far from their scientific pursuits? How far, in fact, do you think that the carelessness was the result of scientific enquiry, and how far of individual character?—I think that nationality has something to do with it.

Dr. J. Anthony, M.D.

25 Oct. 1875.

2584. I am anxious, as you had personal knowledge of Sir Charles Bell and his work, to ask you one or two questions on that point. I suppose that although Sir Charles Bell did not actually experiment before his students he used to describe his experiments before the students?—No. I am not conscious that in any of the lectures that I ever attended of Sir Charles Bell he went into any details of how he had done the experiments.

2585. I did not mean to ask whether he went into details; but when he was talking about the functions of the anterior and posterior roots of the nerves, I presume he did not fail to tell the students that his conclusion as to the functions of those roots was based on experiment?—Of course he could scarcely describe them without saying that.

2586. And I presume that he insisted strongly on his experiments as evidence?—Yes.

2587. I ask you the question because the statement has been made before us, or at all events it has been made elsewhere over and over again, that Sir Charles Bell did not think much of the value of his own experiments, and that he thought he could have arrived at the same conclusion without them; is that the result of your experience?—No.

2588. To me it is a very extraordinary statement, and it is to you also, as I understand?—It is a very extraordinary statement to me, and I cannot reconcile it with my own observation.

2589. In point of fact Sir Charles Bell was very proud of his experiments, was he not?—He was.

2590. (*Mr. Hutton.*) You are aware that Sir Charles Bell, in a passage which has been put before this Commission, spoke very strongly indeed of the large number of wanton experiments which were made by physiologists during his time. Are you at all aware to what experiments he alluded, whether to those in this country or in any other country?—I think that he referred to Magendie's experiments. I am not quite sure whether Flourens preceded him.

2591. An opinion has been expressed by one of this Commission, that physiologists are too busy and too fully employed ever to make what could properly be called wanton experiments. Now that, I take it, was not the view of Sir Charles Bell, and I gather from you that it is not your experience of physiologists?—No, I think not. They have an end, and that end I believe to be a good one. It is merely that I regard the end as not justifying the means.

2592. With regard to that experiment of the fallopian tubes, I noticed that Professor Huxley, in putting his question, spoke of that as made for a scientific purpose, but I understood your objection to that kind of experiment to be that it could be made for no scientific purpose, but only for a demonstrative purpose?—No; I must have misunderstood the question if I said so. That was merely taken as one, and many more experiments of that kind would be made by men who were anxious to carry on, say, the experiments of Professor Simpson of Edinburgh and others to a higher degree.

2593. Then it was for a scientific purpose, was it?—Yes.

2594. But you said that you thought they were not made by men adequately educated for the purpose of discovery?—They were made by young men who were not controlled, as I should propose, by men who have shown a particular talent for that investigation. They were probably done for the purpose of gaining a little notoriety.

2955. And without any sufficiently useful result?—Probably repeating experiments, or trying experiments suggested to them by others.

2596. With reference to that hyper-æsthesia of which Professor Huxley has spoken as existing in man, does not it exist in the higher bred lower animals too; for instance, there is almost as much difference in regard to suffering between a high bred dog or horse and a low bred one, as there is between an Englishman and a savage, is there not?—I am inclined to think so; that you have brought both under the

Dr. J. Anthony, M.D.

25 Oct. 1875.

influence of what you may term civilisation. And I think that the human body is continually undergoing alteration, in fact that its functions are kept up to the highest point, and we have every reason to think that the nervous system will participate. Take a case among the animals; take the pointer or setter; you have elevated its condition of smell, and the development of the small bones of the nose, and the distribution of the membrane, and you have reason to believe that as you have educated that dog you have brought him under the particular conditions of the influence of civilisation, and so his feelings would be modified.

2597. Do you think it would be possible to exclude from the number of living animals liable to experiments animals likely to have that kind of hyperæsthesia; and that if dogs and horses were excluded the suffering would be diminished thereby?—I do not think that, taking the mere genus, it would necessarily follow that all the animals would be of the same excess of sensation. Take the bull-dog; I believe that the bull-dog and the Italian greyhound would be entirely at opposite ends of the scale, though they would be of the same species.

2598. I merely meant that if you were to take two large species and exclude them altogether from experiment, such as the dog and the horse; would not that exclude the animals most liable to extreme suffering; would it not be possible by excluding horses, dogs, and cats generally to diminish very largely the amount of suffering?—I think you might very fairly take the amount of intelligence as almost a measure of the sensation. Provided you found any particular animal, whether high up or low down, very intelligent, you would generally find that the amount of pain it would suffer from an operation would be in proportion to the intelligence. Where instinct obtains to a large extent, there we find, so far as our experiments have gone, an absence of suffering.

2599. I think I understand you to say that if the more intelligent animals were excluded from experiments, it would be also an exclusion of animals who suffer most?—Yes.

2600. (*Chairman.*) And also the animals whose nature approaching most nearly to man, would be the animals on which the experiments are made for illustrating the probable effects on man?—Yes.

2601. (*Mr. Forster.*) With reference to those cases which have come before you of young men who have tried experiments which you thought were unnecessary, as you say carelessly and thoughtlessly, do you or do you not think that if a law was passed making such experiments illegal, that would prevent their doing it?—It would prevent their doing it.

2602. With reference to the definition of the pain of an animal, Professor Huxley drew a distinction between men and animals in this respect, that the animals have much less anticipation of pain; but animals have some anticipation of pain, have they not?—Yes, a dog when once whipped, for instance, has.

2603. Or for instance, a hare hearing a dog bark, would be likely to expect the misery that would follow from being hunted?—There the old question comes up of instinct and reason, which is of course an exceedingly difficult question. I think if you take the definition which I gave, the amount of intelligence, the amount of the reasoning or thinking power, that may be taken very fairly as an indication of the amount of the susceptibility of that animal to pain. There may be other points on which it might depend, but it may be taken as holding good in a general form.

2604. (*Lord Winmarleigh.*) Would a monkey suffer pain more than a dog?—I think a chimpanzee, very high in its organisation, would suffer more than one of the commoner monkeys; and the higher the reasoning power of the creature you may take it that the more delicate it is, and the more susceptible it is of the suffering which we understand by pain.

The witness withdrew.

Mr. J. Burdon-Sanderson, M.D.

Mr. J. Burdon-Sanderson, M.D., recalled, and further examined.

2605. (*Mr. Forster.*) I do not know whether you could give us a little more in detail your idea as to the amount of vivisectional experiments that are now carried on in England?—I should like very much to do so, if I can; and I think there are data for giving that information pretty correctly.

2606. May I ask you to draw a line, if you can do so, between vivisection properly speaking, that is, cutting up animals, and the experiments in giving them diseases?—I will. With respect to the amount of physiological investigation that is going on in England one may come to a very correct conclusion from various sources: First, from considering the number of communications which have been received by the Royal Society on physiological subjects. I have made a list of those communications, and I find altogether, in 20 years, 18 or 19 communications on physiological subjects, some of which would involve vivisectional experiments, many of them, however, not. There are five I think altogether, counting all that would require experiments on animals, and including two where the experiment would only amount to the taking of blood from the animal.

2607. I understand your answer to be that there were only three papers in the last 20 years published in the Philosophical Transactions of the Royal Society, which would involve painful experiments?—Yes. One may take another source of evidence which is equally good; there exists in connexion with the Royal Society, a Government Grant Committee, the grant being an annual one administered by the Royal Society for the advancement of scientific research. I have run through the grants which have been given to different persons on their application for the making of experiments of a physiological kind, and I have got a list of only ten persons who have received grants for physiological investigations at all; and of these, six only are of such a nature as to involve vivisection as it is usually called. There is another grant which exists at present, one dependent on contributions from medical men, administered by a committee of which I am also a member, and which has for its object the making of investigations with reference to the action of remedies. From these three sources I am able to form a very correct opinion as to the number of people who are actually engaged in this country in physiological investigation. About the time that Dr. Sharpey was giving evidence here, we went through the number together, and at that time we calculated that in England and Scotland there were about 13 persons now engaged more or less in physiological investigations in this country. I think I may make it up, by taking a great deal of pains, to 15 or 16. I have got the names here. I should prefer to give the names. (I have not got them in any order). Dr. Yule, Dr. McKendrick, Professor Dewar of Cambridge, Professor Rutherford of Edinburgh, Professor Arthur Gangee of Manchester, Dr. Caton of Liverpool, Dr. Michael Foster of Cambridge, Dr. Pavy of Guy's, Dr. Pye Smith, Dr. Brunton, Dr. Ferrier, Dr. Fraser, Dr. Crichton-Brown, Dr. Klein, and Mr. Garrod. I have put the names of four or five gentlemen who really are not in any sense engaged systematically in physiological investigation.

2608. (*Mr. Hutton.*) Dr. Wickham Legg you have not mentioned?—I ought to have put him in; I forgot him; but the number of investigations in which he has been engaged is small.

2609. (*Mr. Forster.*) This is the number of gentlemen that are engaged to your knowledge in physiological investigation?—Yes.

Mr. J. Burdon-Sanderson, M.D.

25 Oct. 1875.

2610. (*Lord Winmarleigh.*) As you are giving the whole list, had you not better put in your own name too ?—Yes.

2611. (*Mr. Forster.*) Those gentlemen may, or may not, according to the nature of their investigations, feel that they ought to resort to experiments ; it does not follow that they all will ?—Not that they all will, but that they all have. Every man who makes physiological investigations must more or less use animals ; because clearly physiology is a subject that deals with living animals, and not with dead ones.

2612. Do you think it at all probable that there are other physiological investigators through the country who would not have come into communication with either you or any of those gentlemen whom you have mentioned, so that you could know their names ?—I think it is very improbable.

2613. We have had it stated in evidence by one gentleman that he had reason to believe that a good many young men, young practitioners, are trying experiments simply for the object of finding out whether a thing is or is not as it is stated. Have you ever heard of that ?—I have directed my attention particularly to that question. I have had a great deal to do with students at different periods of my life, and have now a great deal to do with them, and I must say that I have never met with any tendency on the part of students to make experiments. And further I would say that students have told me themselves this, with reference to experiments on animals, that in those schools where a certain number of properly conducted experiments are made under the regulations which I explained at the last sitting, that very fact takes away from them that desire to make experiments themselves which they might otherwise have felt; because they see that making an experiment is a very serious matter ; that it involves a very great deal of exactitude and a great deal of preparation, and that in order to its being done effectually it must be done with the utmost possible care ; and that at once tends to discourage men from making idle investigations of their own.

2614. The evidence we have received is not at all applicable to the students of physiology, but the witness was speaking of young medical practitioners who were making experiments, such, for instance, as tying up the Fallopian tube of an animal in order to see what would happen ?—I do not think that is the case ; in fact I am certain that if it is the case, it must occur very exceptionally, and without any reference whatever to physiological investigation.

2615. (*Mr. Hutton.*) Are you not aware of one case which we are both aware of (I do not wish to mention the name) of a young man whom you would think very incompetent to make those experiments, and who admitted to us that he had a laboratory of his own in which he did operate on living animals ; of course you know to whom I refer, though I do not wish to mention the name, a man who had been studying under Dr. Klein ?—I should imagine that he had done very little in the way of experimentation himself. It was stated I believe, as far as I remember, that he had repeated a certain experiment with respect to which he had elsewhere expressed himself in very condemnatory language. I remember that circumstance ; but whether he made many experiments I do not know.

2616. He stated that he had a laboratory of his own in which he operated with the greatest care to prevent pain, but that he had a regular laboratory of his own ?—He certainly has published nothing ; no fruit has come out of his labours.

2617. I was simply going to ask you whether you do not think that that case is much commoner than you suppose it to be ?—I do not think so. I know one instance of a gentleman who has made a certain number of experiments on animals of an injudicious and useless kind. He is a man who entertains peculiar notions as to the action of certain remedies, and he wished very much to find out something about them. All I can say is that I had a long talk with him and did my best to persuade him to make no such experiments again, and I think that that advice was followed. I do not think that the thing has happened again.

2618. (*Mr. Forster.*) Then with regard to experiments for the purpose of teaching, I think I understood you to say that they were conducted with anæsthetics, with the one exception of the experiment of showing the action of poisons ?—The exception that I wanted to make was not that we physiologists, or rather those who are engaged in teaching physiology, would have to make such experiments, but that those gentlemen who are specially engaged in teaching the two subjects of the action of remedies, (I mean the physiological action of remedies, which is called pharmacology,) and the action of poisons, might find it necessary to exhibit the action of certain bodies, either remedial agents or poisons, without using anæsthetics, but I stated distinctly that so far as the illustration of a course of physiology goes, it is possible to make a sufficient number of experiments completely under anæsthetics, which are sufficient for the illustration of the great facts relating to the leading functions of the body.

2619. Then I think I gather from these two answers together, that any law which stopped teaching experiments, except with anæsthetics, and which allowed licences to be given to physiological investigators of competence to perform experiments, with certain restrictions, provided that those restrictions were reasonable, would not interfere with physiological science in England ?—Yes.

2620. You stated that the toxicological experiments would not give pain for any length of time. I am so ignorant about it that I should like to know what length of time ?—I must take an instance for that. You mean, as I understand you, toxicological experiments for demonstration. It is difficult to limit the time, but it is a time which would be expressed in minutes.

2621. In a strychnine experiment how long would the animal be under the agony of strychnine before its death ?—It would depend entirely upon the dose.

2622. But in order that the experiment should be clearly shown ?—Five minutes.

2623. You have the management of the Brown Institute under the direction of the London University ? Yes.

2624. Are the experiments which you practise done upon animals connected with that institute ?—Not at all ; not in the slightest degree.

2625. Are there any experiments in that institute upon animals ?—The only experiments that have been made there, as has been already explained fully elsewhere, are experiments relating to histology. Certain experiments were made there on inflammation which had to do with investigations in progress, and some of the results of these experiments were shown to certain gentlemen, with one or two exceptions, members of the medical profession, who were Dr. Klein's private pupils. It was understood that these experiments were made privately, that is to say, that the case was that of a number of skilled men working together at an investigation ; but there was some misunderstanding with relation to that question. Consequently it is not possible for me to say that there have been no experiments made there ; but no experiments of a physiological kind have been made in connexion with the business of the institution.

2626. What is the object of the institution then ?—The object of the institution is twofold. It is stated in Mr. Brown's will to be to investigate, and, if possible, to cure the diseases of animals. Up to the present time the institution has consisted of a hospital for the reception of out-patients and in-patients and of a laboratory of research ; and now we are endeavouring to extend it by establishing relations with another society with the view of conducting investigations as to diseases of the animals of the farm, and we hope shortly to be able to extend the usefulness of the institution in that direction. We

Mr. J. Burdon-Sanderson, M.D.

25 Oct. 1875.

have made extensive investigations at the Brown Institution, many of which have required the use of animals, particularly with reference to tuberculosis and to the question of the nature of fever. We have been lately investigating cancer, and also typhoid fever, but these do not come within the category.

2627. (*Chairman.*) But is cancer a disease of animals?—Cancer is very largely a disease of animals, though it cannot be induced in animals. We have it in many cases in animals.

2628. (*Mr Forster.*) Putting aside for a moment the effect upon human beings, do you or do you not consider that the physiological experiments which have been made upon living animals will tend to diminish the suffering of animals generally?—I can only answer that generally, namely, by saying that an increased knowledge of the nature of disease, and of the action of remedies, will most unquestionably diminish the suffering of animals; and further that the diffusion of knowledge among veterinary practitioners will enormously diminish the suffering of animals, and that this is likely to be the result of the direction of the attention of scientific men to their diseases.

2629. There have been experiments on sheep-pox, have there not?—There have.

2630. Do you know anything about them?—Yes; they have all been done in co-operation with myself.

2631. Do you think that these experiments bring any reason to suppose that we shall be able to diminish sheep-pox?—No; the object of investigating sheep-pox was entirely to acquire a knowledge about small-pox, because the one disease is a picture of the other.

2632. The knowledge that you gain of sheep-pox would not help then in the remedial treatment of that disease itself?—No; the case of sheep-pox is this, that you can get rid of it by inoculation. When sheep-pox prevails the animals are inoculated in large numbers and in that way rendered incapable of sheep-pox, and inoculation can be done in such a way as not to endanger the animal's life.

2633. Then you would not say that the race of dogs for example had gained by the sufferings to which any particular dog has been exposed in these experiments?—No; certainly not, not directly, excepting in the way that I have mentioned just now. Indirectly the increase of knowledge is beneficial to the dog as to man.

2634. (*Sir J. B. Karslake.*) In regard to that work which has been referred to, the handbook which you edited, might I ask what the date of the edition is?—1873.

2635. That is the only edition, is it?—The only edition.

2636. In that work, where you speak of the use of curari, was it assumed at the time that it was an anæsthetic?—No; I think not.

2637. That curari was not assumed to be an anæsthetic; but where it is mentioned it is mentioned as being a substance which would be used for other purposes than as an anæsthetic?—Yes; it is mentioned entirely with a view to its other actions, no doubt.

2638. You told us the other day that that book was written for the benefit of those who had advanced in their studies to a certain extent, and who were commencing physiological research?—Yes.

2639. Now does that book anywhere recommend the carrying out of the experiments which are referred to there as a part of education?—I am not aware that it does.

2640. Of course the book will speak for itself, but I merely want to have it one way or the other, whether the particular experiments which are mentioned in that work are recommended as being experiments which ought to be practised, or are merely statements of experiments that have been tried with particular results?—I think it must be admitted that although with reference to some of the experiments it is distinctly recommended that they should be shown, and with reference to others it is clear that they are not intended to be shown, it is not sufficiently distinctly stated which might be with propriety shown, and which not. In one part of the book the different classes of experiments with reference to that are distinguished by asterisks, but that is not the case as regards the rest of the book.

2641. The intention then is that a certain class of those experiments, notwithstanding that the results which it is desirable to obtain from the experiments have been clearly obtained, should be shown to students?—Yes, certainly.

2642. And in other cases it is not intended that those experiments should be shown to students; but the facts are mentioned in order to give general knowledge and acquaintance with the facts which are there disclosed?—Yes.

2643. Now in the cases where it is not intended that the experiments should be shown to students, but where facts and phenomena have been clearly demonstrated by experiments, in your judgment would the disclosure of those experiments rather tend to prevent or diminish vivisection in those cases than to increase it?—I think it would.

2644. In cases where you have described an experiment and the result is clearly shown, would it generally speaking be taken by physiologists that up to that point, unless there is something to disturb what you have stated there, the fact has been clearly ascertained?—Certainly.

2645. And in those cases you would rather assume that the series of experiments, or the particular experiment, by which that fact has been ascertained would not be resorted to again?—Certainly.

2646. In that sense the disclosure of the experiment would rather tend to diminish vivisection for the purpose of establishing the fact than to increase it?—I am quite certain that explanations of that kind have had that effect.

2647. And in writing books of that description for physiological students and others, is it necessary to describe the experiment and the result in order to give the full information as to whether the experiment leading to the result has been satisfactorily performed or not?—Certainly it is necessary. I would illustrate that by saying that in every lecture on physiology one always states the experiment as well as the result which has been founded upon it; and one always makes the conditions of the experiment as clear as one can to the students without reference to its being shown to them.

2648. Now in certain cases I understand you to say that the experiments have been performed, and it is stated that the experiments have been performed, and that satisfactory results have been ascertained, only up to a certain point?—Yes.

2649. In those cases do you think that the description of the experiment which has been performed and the result which has been clearly ascertained, give a basis and standpoint from which further experiments would be performed?—Yes, I think so.

2650. Without resorting to the old experiment for the purpose of ascertaining what is stated to have been clearly ascertained up to that point?—Certainly.

2651. How long have you been engaged in lecturing?—On physiology since 1866.

2652. How many courses of lectures in the year do you give?—One course.

2653. Consisting of how many lectures?—75 lectures.

2654. In how many of those 75 lectures would it be necessary to introduce experiments on a living animal?—None; I never make any such experiments during my lectures. I never make any experiments on animals in connexion with my systematic course. With reference to those special exceptions which have been mentioned, which relate as I say to the most important functions of the body, all of those experiments are included in perhaps two weeks or three weeks of the so-called practical course. In this case the experiment constitutes the whole of what is done on the occasion. I may as well explain, as plainly as I can, what my practical course consists in. I think

Mr.
J. Burdon-
Sanderson,
M.D.

25 Oct. 1875.

I shall not be wasting time by doing so. My practical course extends over about 11 weeks. Of those 11 weeks about five weeks are occupied with chemical experimental demonstrations which do not involve any experiments on animals. About half of the remainder, that is to say, about two or two and a half weeks more, is occupied with the discussion of the physics of the nerve and muscle, which also does not involve experiments on animals but on the living tissues of dead animals. The other two weeks are usually devoted to the consideration of the functions of circulation and respiration; and within those we are able to show a certain number of experiments, all of which as I stated before can be performed on animals perfectly anæsthetised, or on animals in which the brain has been destroyed.

2655. Now might I ask you this question: in one of those courses of lectures, what is the number of animals, or about the number of animals, sacrificed?—I may state that we use for these purposes only rabbits and frogs. I do not wish to understate it; certainly it is not more than five or six rabbits.

2656. You use frogs as well you say?—We use frogs.

2657. Anything else besides rabbits and frogs?—No. I have used dogs also anæsthetised, but it is not necessary; one can do without using dogs for the particular experiments to which I refer.

2658. Of course different people may have different opinions on this subject; but in your judgment, as the person responsible for the education of those under your charge, could you, in your opinion, make that plain to them which you desire to communicate to them, without showing those experiments upon animals?—No, I could not. I could make it plain to them, but I should be under great disadvantage.

2659. Do you think your teaching would be as perfect unless you had the opportunity of showing the experiments as it is having the opportunity of showing the experiments on animals?—I think it would be much less perfect.

2660. (*Lord Winmarleigh.*) What is the usual length of your course?—A systematic lecture always lasts an hour, but, as I said, at systematic lectures no experiments are done. A demonstration must always last a longer time. May I ask, am I to limit myself in my answer to those demonstrations in which an experiment is required?

2661. You stated that your course lasted 11 weeks, and I meant to ask you especially the length of those lectures with demonstration?—Usually about half an hour.

2662. (*Mr. Huxley.*) To go back to this question of the handbook for beginners: there is a common impression that the meaning of that is, that any young man who feels inclined to study physiology, whether he has had any previous education or not in that direction, is to take up your book and go and try to do the experiments; was that your intention?—Certainly not.

2663. I apprehend in the first place that it is called a handbook "for the Physiological Laboratory," under which circumstances it is a tolerably clear conclusion that it is meant for the use of persons who are at work in a physiological laboratory?—Yes.

2664. To you and to me the sense of the words "physiological laboratory" is perfectly familiar, and we know that is a place under the direction of a skilled physiologist?—Yes.

2665. So that on the face of it, from the title of the book, it would convey to you and to me a clear impression that it was meant only for those beginners who were commencing that work in a physiological laboratory?—Yes.

2666. Then I ask you whether the book is not something very much more than a handbook for a beginner. For example, I myself am in the habit of using it in this way—that when I want to know what the experimental basis of any physiological doctrine is I turn to your book, and I find there an account of the exact matter of fact upon which the higher conclusions of physiology are based. I presume that use of it is a proper one in my hands?—I think it is.

2667. And one intended by the authors of the book?—Certainly.

2668. So that this book is not only a handbook for the laboratory, but it is meant as a kind of statement of the objective basis of physiological doctrine?—It is.

2669. I think you have already said that, so far as your knowledge of medical students goes, you do not find in them any disposition to do much in the way of experimentation themselves?—I have never observed any.

2670. Perhaps I might say that it is your feeling as a teacher that you would be a little better pleased with them if there were some zeal shown in that direction more than there is?—I should.

2671. So far from there being any need to restrain the average medical student in the direction of doing work, the practical difficulty known to every teacher is to get him to do the work that he ought to do?—Yes.

2672. Now there seems to be a prevalent idea that the kind of physiology dealt with in your book, and in such books as yours, is something new. Your memory does not go back, I suppose, quite so far as mine, but still you would be able to say if, 30 or 35 years ago, there was not a method in great use of exactly the same character; I refer, for example, to Marshall Hall's experiments and Sir Charles Bell's experiments in this country; they were pursued upon just the same method as those recommended in your book?—Exactly the same method.

2673. In fact there was no other way of ascertaining the facts which they ascertained except by experiment?—No.

2674. Now as regards the experiments in elucidation of pathology, my teacher, Mr. Wharton Jones, somewhere about the year 1845, that is 30 years ago, was to my knowledge (I must ask you whether it is to your knowledge also) engaged in experimental inquiries as to the primary phenomena of inflammation?—I know his researches very well indeed.

2675. So that there really is nothing new in these methods?—No.

2676. Nor anything that can be regarded as an innovation upon the established customs of physiologists?—There is no difference in the methods excepting that they are more complete than they were before.

2677. Then there seems to be a very prevalent idea that it is physiology alone which has of late years been developing this practical investigation in teaching. Now, I think you will confirm me by answering in the negative a question that I am about to put to you, namely, whether 40 years ago there was in this country a laboratory of practical chemistry in which students were trained in practical chemistry?—It is not necessary to go so far back. In Edinburgh, when I was a student, which is not so long ago as that, in 1850, there were no means whereby students could work practically in chemistry, in a laboratory in research, even in Edinburgh.

2678. As regards physics you are aware that recently the Duke of Devonshire has established a physical laboratory in Cambridge, and that within the last 10 years a very fine physical laboratory has been established in Oxford; but I think it will be within your knowledge that 20 years ago there was no physical laboratory in this country to which students had access, and in which they were regularly trained?—I think there was not.

2679. So that in point of fact the development of the teaching of physiology in the practical direction is nothing special to physiology itself, but is only part of the great movement which has affected all branches of physical science, and of the conviction at which men of science have gradually arrived, that there is no teaching of physical science worth anything as thorough teaching unless it is accompanied by practical instruction?—Quite so. I should like to add, Mr. J. Burdon-Sanderson, M.D.

25 Oct. 1875.

with reference to my opinion, that in the future physiological research will be carried on more in England than it has been carried hitherto, that the ground which I have for thinking so is that the study of physics and chemistry is now pursued under greater advantages than before, and that there are a greater number of young men practically conversant with those subjects on which physiology is based.

2680. Then is there not another consideration which tends very much to lead one to think that in course of time the number of persons who undertake private investigations will be much limited, and that the investigations will, as a matter of course, be confined more or less to physiological laboratories; I mean this consideration—that as research is carried on into the more difficult parts of physiology the investigator requires appliances of greater complexity, which are exceedingly expensive, such as time-registering instruments and the like; and that not only are those very commonly out of the reach of the private investigator as a matter of expense, but that even if he could afford to buy them he would have to build a place adapted for their use?—I am certain that that will operate in that direction.

2681. So that the natural tendency of physiological research is to get itself, so to speak, into laboratories provided with these means and appliances? — Precisely so.

2682. Then again, I think you expressed the opinion just now that the more clearly students are instructed in the experimental method the more they learn of what requires to be done to carry out experiments successfully, and the less likely it is that they will attempt them themselves unless they are properly instructed?—I think so.

2683. That is to say, any man of decent intelligence will understand that it is a perfectly useless thing for him to attempt to waste his time over the repetition of these experiments unless he has not only the manual dexterity which is required, but unless he has the apparatus also?—Yes.

2684. For instance, there is a sort of notion afloat that a student who gets your book into his hands immediately sets to work to repeat all the experiments he finds in it. Now I presume that, taking a rough estimate, some half or three quarters of those experiments could only be performed if a man had access to considerable instrumental aid? —Certainly; that is certainly not over-stating the matter. There are very few of the investigations which can be conducted without exceptional instrumental aid.

2685. So that in fact what it comes to is this—that so far from sound instruction in the experimental method tending to make students reckless, or even to increase their desire to try experiments, the distinct tendency of that instruction in your opinion will be to render them less likely to try these experiments, more likely not to try them, except in physiological laboratories where they have the means and appliances, and where they are under superintendence?—Certainly.

2686. I understood you, in reply to questions which were put on the last occasion, to give a sort of general approval to the Bill which was proposed by Dr. Playfair, in the sense that you did not actively object to it?—Yes.

2687. That, however, if I may judge by the feelings that have been expressed to me by other scientific men, does not imply that the Bill met with your active approbation, or that you entertained any conviction that legislation was necessary?—I think that legislation is not necessary with relation to organised physiological research, and I do not know any reason for thinking that it is necessary on any other ground.

2688. I understand you to have said that in your belief there is no wanton or cruel experimentation practised in this country?—None to my belief.

2689. And so far therefore as the ordinary grounds for making new laws are concerned it would not appear that there is any case for legislation at all?—No, I think that it is so.

2690. Then taking the particular kind of legislation which is proposed, and looking at it from the general point of view of the way in which laws ought to be made, there are one or two questions which I should like to put to you. Some years ago it was thought expedient to pass an Act for the restriction of the sale of poisons; no doubt you recollect the fact?—Yes.

2691. I do not know much of the details of the Act, and I have nothing to say about the Act itself. Suppose, however, that the framers of that Act had so drawn it that all the pains and penalties of the Act fell upon the medical men who do occasionally use poisons for the benefit of mankind, and at the same time left everybody else free, so that if a medical man used poisons he should be liable to penalty or restriction of some kind, whereas all the rest of the world might buy poison to any extent and use it as they liked; do you think that an Act of that kind would have commended itself to the common sense of the legislature?—Certainly not.

2692. Do you not think that the medical men who were affected by such an Act might have very justly said that it was injurious to them, and threw a most unjust slur upon them?—Yes.

2693. Now to apply that to the legislation which has been proposed in this case, what I apprehend to be proposed is this, that the infliction of pain for certain purposes upon animals, such infliction being held by the persons who inflict it to be for the good of mankind, shall be either altogether stopped or placed under certain restrictions, while the infliction of pain by all the rest of the world for totally different motives, in many cases for the purest amusement, shall not be touched at all. You will understand that I refer to the fact that such Acts as these restrain men of science from experimentation while they leave untouched all that vast amount of infliction of pain upon animals which goes under the name of sport. Now I would ask you whether within your knowledge the principle of such legislation as that is not regarded by men of science as unjust in itself and as casting a slur upon them as a body?—I certainly think that it is. I think that it is felt that the same principle ought to guide legislation in respect of all other occupations, whether connected with sport or not, which produce pain, as it is proposed to apply to the case of experimentation upon animals, without taking into consideration the circumstance that we are working for an important and good object.

2694. Now in case it should be said that there is no parity between the sort of pain inflicted in the two cases, I would beg you to put before the Commission your opinion as a physiologist as to some examples which I will put before you. I understand you to say that while you yourself as a physiologist hold that it is perfectly lawful and justifiable to inflict pain upon animals where you have any reasonable prospect of obtaining thereby a considerable advance of knowledge, yet that you are, on moral grounds, as much opposed as anybody can be to the infliction of pain, unless you have some such definite object; that is so, is it not?—Quite so.

2695. Then I would ask you whether, if a physiologist proposed this experiment, you would think it one which was justifiable for him to carry out. Let us suppose that he took a hare, that he contrived some sort of place in which the hare could run round, a covered gallery we will say, that he set off a machine to frighten the hare very much, which should run as fast as the hare at first, but to a certainty in course of time catch the hare, and then after the animal had gone through all the agonies of fear or exhaustion, should proceed to crush the life out of it. If that experiment were proposed by a physiologist, I take it that you would consider that there must be some demonstrably important truth to be brought out before that would be justifiable?—It would be most unjustifiable, unless the result was of extraordinary importance.

Mr. J. Burdon-Sanderson, M.D.

25 Oct. 1875.

2696. So that if any physiologist did that for the mere sake of getting amusement out of it, you and all physiologists, I suppose, would look upon it with great reprobation ?—Yes.

2697. And yet the hypothetical case which I have put to you is practically a description of the ordinary practice of coursing, is it not ?—I think it is. I have been in the habit of coursing myself to a great extent in former years, and I think it is a true description.

2698. I will put to you another case. The Secretary of the Society for the Prevention of Cruelty to Animals was before us the other day, and he told us with great horror, of certain experiments which have been performed in relation to asphyxia. I am not sure whether 30 or 40 animals might not have been sacrificed ; however, the person who performed these experiments had a definite scientific object in view. Are you acquainted with what usually happens when rabbits are snared as they are by countless thousands in this country ?—Yes ; I know it very well.

2699. And you can tell us as a physiologist what happens ; will you be so kind as to do so ?—In snaring rabbits it may happen that a rabbit is quickly killed, but in a great many cases it does not happen, and consequently if you go into a rabbit warren at night you always find (as I have had the opportunity of ascertaining very lately) that many of the rabbits are not killed by the snare, and they consequently remain in agonies for a long time ; but as you mention the subject of catching rabbits, there is no doubt that the torture which is inflicted by the snare is not nearly so great as the torture which is inflicted by the trap, which is used even more largely. Not long ago I was in Scotland, in Ross-shire, and there happened to be near the house where I was staying a rabbit warren, and I had the opportunity of inquiring into this matter. On that warren some 3,000 rabbits are killed in the year, and I learned from various persons that as you passed the warren you could hear during the night, the cries of the animals.

2700. I have only one other question to ask you on this topic, and that is this ; I presume that physiologists might consider it desirable to experiment on the effect of gunshot wounds, and to inflict gunshot wounds for the purpose of experiment ; but still I presume that in that case also you would consider that any man who undertook an investigation of that kind should have exceedingly clear and definite perceptions of the advantage to be derived from such an inquiry before he entered upon it ?—I understand you to mean the effects of gunshot wounds on living animals.

2701. Yes ?—Such a mode of investigation would be of course unjustifiable, excepting as I stated before, with reference to some result of extraordinary value.

2702. I presume with your large experience of physiological laboratories, you are able to tell us whether any experiment you ever saw in a physiological laboratory is likely to have inflicted the same amount or a larger amount of pain, I would rather say, than that which is inflicted by an ordinary gunshot wound ?—If the animal survives, you mean ?

2703. Yes ; supposing it to be hit in a not vital part ?—It is difficult to estimate that. It so happens that in connexion with my known interest in the diseases of animals, it has twice lately occurred to me that gentlemen have sent me hares which they had supposed to have been suffering from epizootic disease, in which I found shot corns lodged in the serous cavities, which had produced serious inflammation which had lasted of course over a long time. It is quite clear that in such a case as that, the injury so inflicted, of course perfectly unnecessarily, had given rise to a great deal of pain on the part of the animal. No doubt in every hundred rabbits, for example, that are shot, a very considerable percentage are wounded and escape to their holes to suffer. But it is not possible to estimate the amount of suffering so inflicted. It must be very great as compared with the amount of any suffering that we ever inflict. If you take that one means of inflicting suffering, the number of rabbits made to suffer in that way clearly must be enormously greater than the number that suffer in physiological experiments, and the amount of suffering inflicted must be also of a very serious kind.

2704. (*Mr. Erichsen.*) The other day you gave us an illustration of the importance of physiological investigations or experimental inquiry ; you illustrated it by pathological research as an application of experimental inquiry to the elucidation of various pathological phenomena. Is it your opinion, or have you any view upon the subject, that for the future we can only hope for an advance in real knowledge of disease through means of that kind or of an analogous kind ?—It is my profound conviction that a future will come, it may be a somewhat distant future, in which the treatment of disease will be really guided by science. Just as completely as mechanical science has come to be the guide of the mechanical arts, do I believe, and I feel confident, that physiological science will eventually come to be the guide of medicine and surgery.

2705. In relation to hygiene, to therapeutics, and to all other methods employed for the treatment and cure of disease ?—Yes, in relation to three things, the prevention of disease, the introduction of new remedies, and the investigation of their action.

2706. And that if we are to obtain anything like precision in our knowledge of remedies it will only be through the medium of physiological investigation ?—I feel confident that it will be so.

2707. That the disturbing agencies in a diseased condition of the human frame are such that it becomes quite impossible to determine the true action of any remedy when applied to such a frame ; we see certain results, but we do not know how those results are produced ?—Exactly so.

2708. And with regard to the true nature of disease, that knowledge which is derived from an investigation of the dead body, do you think that there is very much more to be acquired by ordinary dead-house observation, the rude pathology in fact that was practised and that is practised more or less in ordinary post mortem examinations ?—During a period which may be said to be now drawing towards a close there can be no doubt that the nature of disease was elucidated to an extraordinary degree by post mortem investigations ; but as you have said the amount of knowledge which we can gain by that mode of investigation is getting exhausted, as we find, by the repetition and repetition of the same facts. Now we have come to a period at which what we want to know is how processes occur, and what are their relations to each other.

2709. That there is, in fact, something like a finality in that knowledge, in the knowledge acquired by the ordinary dead-house investigation ?—Yes.

2710. And that future progress is to be made through other channels ?—Yes.

2711. Those channels may be microscopical investigations and physiological experiments ?—Yes.

2712. And possibly other methods ?—Yes ; exact observations of different kinds.

2713. And observations based on experiment, I presume, also ?—Yes, no doubt.

2714. Then there was another point on which you could give the Commission some little information ; it was in reference to the students who frequent your different classes. I take it that the students who frequent or who attend the class of ordinary systematic physiology at University College are those medical students who simply wish to qualify themselves to become practitioners ?—Exactly.

2715. They constitute at all events the great bulk of the pupils attending your classes of systematic physiology, and they also constitute the great bulk of the students attending the demonstration class, do they not ?—Yes.

2716. But does any considerable proportion of those students attend or work in the physiological laboratory ?—None ; because it never happens that a man becomes what I call a worker in the physiological

Mr. J. Burdon-Sanderson, M.D.

25 Oct. 1875.

laboratory until he is very much more advanced than that.

2717. Is it not the case that many workers in the physiological laboratory have passed altogether beyond the state of pupilage, that they are qualified practitioners of medicine, that they have passed their examinations?—Entirely so, it is rarely otherwise.

2718. And that officers in the Army and Navy in Her Majesty's service frequently come there in order to improve their knowledge of the higher branches of their profession?—It has several times happened so.

2719. And that the men who work there are in fact, as a rule, medical practitioners of different kinds, and who wish to obtain a more scientific knowledge of their profession than they have heretofore acquired, and not mere medical students in the ordinary sense? —It is so.

2720. And those men probably find that such physiological knowledge so acquired is of essential service to them in after-life, in the practice of their profession, or they would probably not expend both the time and money that are necessary for the pursuit of that inquiry in the laboratory?—With reference to a certain class of workers that is strictly true. There is another class of workers to whom that does not apply.

2721. And what is the other class?—The other class of workers, a very small class I must say, consists of men who intend to devote either part or the whole of their life to scientific work.

2722. (*Lord Winmarleigh.*) Of no profession you mean?—Of no profession.

2723. (*Mr. Erichsen.*) But yet you find that there is a considerable number, or a certain number at all events, of young medical men who, after they have completed their studies, and passed their examinations, will devote much time and go to a considerable expense in order to acquire a knowledge of the higher branches of physiology?—That is so as regards our workers.

2724. And those men intend in after-life to become practitioners in medicine, and not only scientific men? —Yes.

2725. Consequently we may take it, I presume, that they imagine, whether rightly or wrongly, that the superior knowledge of physiology that they will acquire in a laboratory will be of considerable advantage to them in practice in after-life?—Quite so. I may add to that, that it is my object, particularly in my own laboratory, to connect the studies in the laboratory with those at the bedside in the hospital which is connected with the institution.

2726. In fact that you make them more or less run in the same line with the studies in what are called pathological matters?—Yes.

2727. Is it the case that in all large well conducted medical schools now there are pathological as well as physiological laboratories, so that the men may work in both?—Yes.

2728. (*Mr. Hutton.*) You have admitted that the object of the whole of the school which you represent is to increase very much the class of teaching that is given in physiological laboratories; that you very much lament the fewness of those laboratories in England; is not that so, that your idea is to have in this country something more like what now exists in Germany and France?—I should wish to see a greater number of efficient schools of physiology.

2729. And you would like to see the ordinary practitioners of medicine passing through those schools so far as might be possible?—Before I answer that second question may I fully answer the other? I should not like to see, I should be very sorry to see, physiological laboratories, established in connexion with all the small schools in this country; it would be objectionable.

2730. You would like to see a very much larger number of the ordinary practitioners of medicine passing through the physiological laboratories than now do so, would you not?—No, I should not wish to see that; I do not think it is at all desirable that all students of medicine should have gone through scientific study of that sort. I think that the man to whom it is of advantage is the consulting physician or the consulting surgeon; but I think that it should be confined as much as possible to men who are likely to be advisers, if I may so express myself, in the profession. With reference to medical students in general intended for general practice, the great point is that they should be what we call thorough clinicists, that is to say, thoroughly acquainted with the aspects of disease as seen at the bedside, and that they should be thoroughly up in the technical part of their profession.

2731. But as regards the higher consulting physicians and surgeons, you would wish to see a larger number of them passing through these laboratories, and you would not think them competent to advise on the more difficult cases without it?—No, I would not go so far as that; because as medicine stands at present, it stands on experience, and the man who is most competent to advise is the man of most judgment and most clinical knowledge, in other words, of most experience.

2732. Still my point is, that you wish to see the number of these laboratories increasing, and not decreasing; that you wish to see the education here more like the type of education in Germany than it is?—I do; but I think I must again repeat what I said as to the type of education in Germany. It is not the case at all, that the ordinary medical practitioner there is more educated in this way than our medical practitioners are; but simply that there is a class of men in Germany who work hard at science. I do not want to introduce any German institutions because they are German, but simply because they are efficient.

2733. And you wish to see a higher class of scientific men in the profession also, I understand?—Yes; certainly I do.

2734. And those scientific men cannot be made what you wish them, as I understand you, without passing through the physiological laboratory, at least, not in the best way?—No; I think not.

2735. Now can you give us any idea at all of what I may call the consuming power of a great laboratory like Professor Ludwig's at Leipzig?—I am afraid I cannot.

2736. Can you give me any notion of how many living animals in the year are taken there for treatment?—I really cannot tell you; I really cannot form any idea. I could tell you how many animals are required for a particular research.

2737. In your own most active year how many living animals would have been experimented upon in your own laboratory for all purposes?—I think I had better answer that by considering the number of animals that I have used myself in particular researches. The research which used the largest number of animals of all the researches in which I have ever been engaged, was one to which I have referred before, namely, the one on tuberculosis, and that has extended over a number of years, and I have no doubt that some 200 or 300 rabbits may have been used in the course of that time.

2738. But that was not the only research that you were carrying on at the same time?—The number used in the other researches must have been extremely small. The only one which would form an exception to that perhaps, of any consequence, would be one which I presented to the Royal Society a few years ago, and in which I suppose I may have used 50 animals; I do not know.

2739. You cannot give us any idea, for instance, how many University College Laboratory would use in the course of an active year for all purposes, and of what classes the animals would be?—If I had known beforehand, I could have given you exact information from the book but you will find that the number used for experiments of the so called vivisectional kind is extremely small.

2740. Will you send in a statement of that?—I shall be very glad to do so. It could not be strictly accurate, but it will be accurate within limits.

2741. (*Mr. Forster.*) Giving the number of animals experimented on last year, for instance, and also the sort of experiments; because some of them may not have been as painful as others?—Yes.

2742. (*Mr. Hutton.*) You will divide them into those in which there was no more painful experiment than killing them, and those in which the experiments were of a painful kind?—Yes.

2743. You cannot give us any idea how many Claude Bernard's laboratory would consume in a year, or Ludwig's?—I cannot tell you really.

2744. You cannot give us a fair guess?—I do not think I could give you a guess at all.

2745. (*Lord Winmarleigh.*) Was last year what Mr. Hutton calls a very active year, or more than usually active?—I should think not particularly so, I do not know that it was more one year than the other.

2746. (*Mr. Hutton.*) Now did you verify all the experiments in your handbook yourself, or only those in your own department of it?—Only those in my own department certainly; and there are many cases in which it is stated distinctly they are not verified.

2747. (*Mr. Forster.*) But there are several of the experiments in your own chapter which you have not verified, are there not?—Yes; there are several where that is so stated.

2748. (*Mr. Hutton.*) Taking the whole number in the handbook, could you give us an idea of how many of the whole were painful experiments, and how many not so; how many were either completely under anæsthesia, or otherwise not painful?—I cannot give you any idea; I think I could, probably, in my own part of it, because it relates you see to the great functions, and as to these you have, of course, experiments of more importance. There are many cases in the other part in which one would not be able to say whether it was a painful experiment or not.

2749. Of course you were more particularly responsible for your own part, and you could do that for us for your own part?—Yes, I would do that; I would distinguish between those which could be performed without detriment to the result with anæsthetics, and so on.

2750. Now I understand your position to be that all experiments for a sufficient scientific purpose that are performed by an adequate inquirer without unnecessary pain, are right?—I am glad you have given me an opportunity of answering. My principle about that and all other cases, whatever the purpose may be in which pain is inflicted is simply this, that the question of right and wrong depends upon the relation between the purpose of the experiment and the pain inflicted, and the care which is taken that the experiment shall be done in the most efficient manner. If the purpose is a good purpose, and if the experiment is made in the most skilful way in which it can be made, and if due care is taken that no unnecessary suffering shall be inflicted, I think that the whole thing is a right action; I have no hesitation about that.

2751. I think that you were present when Sir Robert Christison delivered his address in Edinburgh a few weeks or months ago on the subject of vivisection?—You mean in proposing a vote of thanks? I remember the circumstance.

2752. In that address he was showing how very far from hard hearted physiologists are, and he said that there was one experiment which he had entered upon for a sufficient purpose, and from which he had desisted in the middle on account of the agony caused to the animal. You cannot perhaps tell us what that was?—I do not remember what it was: it was an experiment upon some irritant poison I think.

2753. But would you call that unnecessary pain or not? would you say that was an amiable weakness on Sir Robert Christison's part, supposing that the purpose was sufficient, or that it was a conscientious act on his part?—I should prefer not answering that question, with reference to the particular case because I do not remember.

2754. I was only taking it as raising the question with respect to any experiment where you find one inflicting extreme pain?—I think that a man after devising a method which he believes to be the best method that can be used for the purpose, and having considered the pain that is likely to be inflicted, should not desist in the middle because that pain is inflicted; I think it would be foolish to do so.

2755. (*Mr. Forster.*) But would you not consider that if it was an experiment of that exceedingly painful kind, there ought to be the greatest possible reason for its repetition if it is repeated?—I think I have said so before, that whenever much pain is to be inflicted the purpose to be accomplished requires to be correspondingly important.

2756. (*Mr. Hutton.*) But is it not very much a matter of opinion among medical men, and varying very much from one to another, what is necessary and what is unnecessary in these matters? For instance, Professor Rutherford has stated that he thinks various demonstrational experiments necessary which others have told us they do not think necessary at all. Is not that a thing in which the public would have to rely on the opinion of one particular man?—I think that applies to all kinds of conduct; but with respect to the particular instance put before me, I believe there is a general agreement among physiological teachers in this country that for demonstrational purposes, it is not desirable to use experiments which are attended with pain.

2757. There has been a great difference of opinion between yourself and Dr. Swaine Taylor on the subject of poisons. He assured us that it was not necessary even for the sake of showing the effect of strychnine to exhibit it on living animals, and that he had desisted from the practice; that he had drawings so perfect that it was entirely unnecessary; but there I understand you and Dr. Rutherford to differ from him?—I confess I entirely differ from Dr. Swaine Taylor on that point.

2758. My point is this to bring out that not only you differ from each other, but the foreign physiologists would differ very much from you, would they not, on that subject?—I include among those whom I have represented as agreeing in opinion, those who are actually engaged in research. I only refer to men in that position. I was speaking particularly of teachers of physiology just now.

2759. But you see what we have to fear is that as the experimental school increases in this country the opinions that are now held abroad may come with it; and I suppose that is a reasonable fear, is it not?—I do not think that it is a reasonable fear.

2760. I will put this as a test question: Would you think that any physiologist who gave that experiment on recurrent sensibility simply to show his class in a more vivid way the action of the nerves, was going beyond the bounds of reasonable humanity?—I am perfectly certain that no physiologist, none of the leading men in Germany for example, would exhibit an experiment of that kind, because it is an excessively difficult experiment, and quite unsuitable for the purpose of demonstration.

2761. As regards experiments for purposes of demonstration there is likely to be a very general and uniform agreement on the subject in England, as I understand you?—I think so.

2762. Differing only on smaller points?—I think so.

2763. But as regards research you would consider that any pain, supposing it was sufficiently justified, might be inflicted?—Yes, with the proviso that I made just now, that we ought to have constantly in view the object of making it as small as possible.

2764. Now has it ever occurred to you to see any experiments on inducing rabies in dogs?—No, I have

Mr. J. Burdon-Sanderson, M.D.

25 Oct. 1875.

not; I have seen dogs with rabies which has been communicated to them.

2765. But have you ever seen any attempt at artificially inducing rabies in dogs?—No, I have not.

2766. There was a common story, which very likely may have been false, in the papers not long ago, that some physiologist tried to induce it by keeping a dog starved and without water in the presence of food and water, and I believed that failed; but, however, would such an experiment as that, if conducted by competent physiologists, seem to you at all allowable?—It is so extremely unreasonable to make an experiment of that sort from what we know about rabies, that I cannot conceive of anybody competent doing so.

2767. You mean that it could not be induced by any mental action?—No, it could not be induced in that way. I mean that in that case the purpose could be so clearly shown to be a foolish purpose, that it would be an unjustifiable experiment.

2768. It would not be on the ground of torture, but on the ground of the want of scientific knowledge which it showed that you would condemn it?—I think so, because if that pain could be inflicted with a certainty that the human race would be benefitted by it, then a justification would exist.

2769. Or with a certainty that knowledge would be increased by it, would you say?—Yes.

2770. Are there not a vast number of experiments, which are actually given accounts of in the German and French journals, quite as painful as that, or more so, which in your opinion would be justified?—I do not know any such.

2771. Such an experiment as dividing the vagus nerves and others of that kind?—As I explained on Saturday, the division of the vagus nerves simply produces inflammation of the lungs and certain other symptoms not more painful than those of disease.

2772. This is an extract, as I believe, from the second volume of the Archives de Physiologie; a dog was placed under curari, which, I suppose, as regards a dog at least, is not an ænæsthetic; is not that admitted?—I have stated that I myself have no decided opinion on that subject.

2773. The pneumo-gastric and sciatic nerves were dissected out and irritated during six hours. The operators than went away at night leaving the artificial respiration engine working on the dog, which they found dead the next morning, the machine still working upon it. The object of the experiment which was tried by M. Paul Bert was said to be to test how long the nerves would remain sensitive. Of course, I have no special physiological knowledge. I only want to know whether there are not a vast number of experiments of that kind that might be tried with real scientific advantage?—Well, I think, with regard to such an experiment as that, the rule that I have already stated, namely, the relation between the purpose and the good gained must again be the rule of action. What I mean to say is this, from that statement it would seem to me, that the rule had not been conformed with, namely, that it was not done in the most efficient manner, and with a due regard to the least possible infliction of suffering, and therefore that in so far it was unjustifiable.

2774. Now as to those experiments on starvation which Professor Sharpey gave us an account of, and which he seemed to think were justifiable, to try the absorption of the different fluids at the various stages, what would you say?—It is perfectly true that those experiments of Chossat have given most valuable results, which you find quoted in every handbook of physiology. They give us the statistics of a particular process. It is very difficult to say precisely how the rule would apply to such a case as that; but there is no doubt that it would be very improper to repeat experiments of that kind.

2775. Except for the purpose of further verifying. You would not exclude a further verification of a result which was doubted in any degree?—Certainly not, according to what I have already said.

2776. (*Mr. Forster.*) But now with reference to that answer take this particular experiment, would you think that a physiologist would be justified with the present knowledge about that experiment in repeating it?—No.

2777. (*Chairman.*) And if an experiment is a very painful one the disposition to arrive at a conclusion that its repetition was necessary would be very much enfeebled?—Yes; no doubt.

2778. (*Mr. Hutton.*) Take the experiment which Delaroche and Berger have made, "They have demonstrated that in a dry stove the energy of the " duration of resistance is in direct proportion to the " size of the animal. In those experiments which " have been continued until the death of the animal " the heat of the stove has varied between 50° and " 93·75° (centigrade scale)." In fact animals were baked to death to see at what temperature they would die. Those are, I suppose, purely scientific?—Those experiments might, if they were conducted with skill, be, on the one hand, productive of important results, and on the other not be attended with much pain; because an animal, when subjected to a high temperature, very soon comes to a point at which pain ceases. I cannot comment upon the particular experiment, because I do not know it.

2779. The experiment of freezing animals to death you would say the same of, I suppose?—The same thing applies undoubtedly.

2780. (*Mr. Forster.*) Do you consider that either you yourself, or any other of the English physiologists with whom you are acquainted, would in the case of a very painful experiment, such as one or two of these of which we have heard, think yourselves justified in repeating it after it had been established, as we hear these have been established, by the foreign physiologists?—No, not at all.

2781. (*Mr. Hutton.*) But that of course assumes that it was so established. Now is it not the case that scientific investigation constantly reopens questions and finds that they were not established in a way that was satisfactory to the new investigator?—I should like to make a general statement with reference to that. If you take the progress of physiology, I mean during the past 25 years, there is no doubt that it has consisted, in a great measure, in revising statements of facts which had previously been ascertained by less exact observations.

2782. Revising them by the re-making of experiments?—By making experiments under more exact conditions than they were made before that time. I mean that since 1850, or thereabouts, there has been a change, and that that change has consisted in the introduction into physiology of more exact methods derived from physics and chemistry; and that consequently there has been a certain amount of repetition, revision, and re-building up of facts which were previously known in rough outline; and that circumstance explains to us how it is that physiology has made such very rapid progress during that time. But more and more every year our methods are becoming exact, and the more exact our methods are, it is unquestionably true that there will be less and less repetition of experiments made before; and particularly that in Germany, where exactness is really more valued than it is in France (I have no hesitation in saying so), and in this country also, so far as we do a little in that direction, repetition will be avoided by the great care and exactitude with which experiments are made.

2783. Still all the old experiments suggest new ones, do they not, and new ones that are not less likely to be painful than the old ones?—There is no doubt that questions will arise until the science has become an exact science, so to speak.

2784. What would your criticism be on that statement of Mr. Ray Lankester's, that in this, as in every other experimental science, the number of questions raised at every point increases in geometrical progression, so that the numbers of victims to this process must increase in geometrical progression too?—I must

Mr. J. Burdon-Sanderson, M.D.

25 Oct. 1875.

say that I think that that statement was a mistaken one.

2785. A scientifically mistaken one?—A scientifically mistaken one. I may illustrate that in this way. If you take such a book, for example, as the one just published, Hermann's Physiology, and compare that book with a book written 25 years ago, we will say Müller's, you will find in the first place that the book is a great deal smaller; and secondly, that all the statements are a great deal more simple; so that the existing position of physiology can now be expressed in much shorter language than it could then. That implies a diminution in the number of facts, and particularly in the number of unconnected facts. I mean to say that our knowledge is becoming methodised, and consequently that the number of separate facts is smaller now than before.

2786. You would not say, would you, that Ludwig's laboratory tries fewer experiments than any laboratory existing at that place would have tried twenty years ago?—No, because really investigation has been going on with more rapidity during the last ten years in physiology than at any previous period.

2787. And it is likely to go on with still more rapidity?—Investigation may no doubt.

2788. Painful investigation?—I do not see why it should.

2789. (*Mr. Forster.*) You would not apply that answer to giving animals diseases, would you, I mean you would not make the answer that there would be less likely to be experiments for the future, as regards pathological experiments of giving animals diseases?—I think the same answers apply on the whole.

2790. (*Mr. Hutton.*) Are you not on the council of the Medical College of Women, or some such council?—Yes, nominally, at all events.

2791. What is the proper phrase?—I think it is "for the medical education of women."

2792. Now one thing which gave a great impression that vivisection was increasing very much was, that a vivisector was chosen, and a French vivisector, who could not express himself in any very good English, for teaching the young women, when two, an Englishman, I think, and a Scotchman, had offered themselves, who would not have used vivisectional practices. Will you tell me anything you can on that subject. Is it not within your knowledge that an appointment was made there, and, as was said at the time, by your advice, of a gentleman who could not speak English clearly, and whose great distinction had been obtained in the region of vivisection?—I took no active part in the affair at all.

2793. The statement as it was made to me was, that two, one an Englishman and one a Scotchman, offered themselves for the post, that this Frenchman, whose great distinction was in this region of experiments, also offered, and that it was referred to you to decide between them, and that you chose the Frenchman?—All that I did was to express my favourable opinion of Dr. Dupuy as a physiologist, but I did not express any opinion of the others.

2794. Then subsequently Dr. Dupuy resigned, did he not, because the young women would not attend at vivisectional experiments?—I am sorry to say I cannot tell you anything about that, I only attended the initial meetings in that school, in order to give it a push at the beginning; and I am sorry to say I have not interested myself about it since, although my name is on the council.

2795. In effect you know very little about the matter?—I know nothing about the matter since that time.

2796. Just one or two questions about the Brown Institute. You were stating just now that these vivisectional experiments do not take place at all at the Brown Institute; the experiments on living animals, except so far as the induction of artificial disease goes?—My words were, I think, that experiments of that kind are not conducted at the Brown Institution as part of the business of the institution at all, but that a certain number of experiments have been conducted in connexion with Dr. Klein's private teaching. I am speaking of the present state of things, not of the past.

2797. But experiments have taken place in the Brown Institute that were of this kind, have they not, some of Professor Ferrier's?—Yes, as you know, experiments of that kind were done, and after they were completed it was explained to Professor Ferrier that it was not possible for such experiments to be made there; and that has not occurred since, as you also know.

2798. Still this institution was founded expressly for the benefit of animals, was it not, and there is nothing in the whole of Mr. Brown's will that suggests anything that is not for the benefit of animals; is not that so?—Perfectly so; but as you refer to Dr. Ferrier's experiments, I must be excused for remarking that those experiments were made in a room not used for any other purpose, and not used for any of the purposes of the institution; and that it was entirely a private arrangement, just as much a private arrangement as if they had been made in one's own house.

2799. Still, however, as to Dr. Klein's experiments you are aware, are you not, that a good many go on in his private room which are really of a painful class, though not under your direct superintendence?—I have stated what I can about it. I know that he has used animals in the course of his private instruction in histology, and also with reference to certain investigations as to inflammation.

2800. (*Mr. Forster.*) Is the laboratory in which he tries those experiments a room in the Brown Institute?—A room in the Brown Institute.

2801. (*Mr. Hutton.*) Can you tell us how many patients there are in the Brown Institute. I mean the number of animals there for purposes of cure?—The numbers are printed every year; I cannot tell you what it is at present.

2802. Is it true or not that about as many animals are kept there for the purposes of these experiments as there are for the purposes of cure?—There are no animals kept for the purpose of experiments excepting guinea-pigs and rabbits.

2803. And rats?—And rats also; but the rats are kept entirely for anatomical purposes; they are very little used there. The only reason why they are kept there is that they can be kept there more healthy; and the guinea-pigs the same. There happens to be space there for keeping guinea-pigs which is very convenient and suitable.

2804. About the relative number, do you suppose that there are more or fewer animals kept there for the purpose of experiments, than there are for the purposes of cure?—If you count the rats and guinea-pigs and rabbits, of course there are more.

2805. A great many more?—Yes, because patients never present themselves belonging to those species.

2806. The practical result is, that an institution founded expressly for the cure of animals contains more animals subjected to painful experiments than it does animals which are being cured?—No; on the contrary, because these animals that you speak of are kept entirely privately. They do not belong to the institution, and are not kept at the expense of the institution.

2807. They are operated on in the institution?—No, not at all. These animals happen to belong to me; they are animals which I occasionally use at University College. I mean, it sometimes happens that I want rabbits or guinea-pigs, and they are sent for to the Brown Institution. These animals are there in store, so to speak.

2808. You store them at the Brown Institution for University College?—I mean to say that the purpose for which these animals are kept there is an entirely private purpose. They belong to me, and are kept for my objects, whether right or wrong. They have nothing to do with the institution, and are not kept at the expense of the institution, or in any of the stables or places intended for the reception of animals.

Mr. J. Burdon-Sanderson, M.D.

25 Oct. 1875.

2809. (*Mr. Forster.*) How far is the institution of any sort of service in keeping them?—Not of any service, excepting in so far as it affords space. There is not a single shilling of the funds of the institution spent in keeping these animals.

2810. That turns out to be of the greatest possible service, does it not, because you would not know where to put them otherwise?—I could find other places, but it is better for them to be there.

2811. (*Mr. Hutton.*) But it is not only for your own purposes at University College that you kept these animals there; but for Dr. Klein, for the purpose of his private investigations at the Brown Institution, is it not. He takes his supply from the same stock?—Yes.

2812. Practically then, the animals kept there for the purpose of painful investigation are more numerous than the animals kept for the purpose of cure?—If you wish to put that question again, I must give the same answer as before, that if you count these small animals that you have mentioned, it would necessarily be so; (to the Chairman) I am sure Mr. Hutton will do me the justice to admit that I have done the very utmost that I could to give the Brown Institution a practical character for the beneficial investigation of the diseases which affect animals which are most important to men.

2813. (*Mr. Forster.*) The largest number are rats, are they not?—Rats and guinea-pigs.

2814. Are they kept for the purpose of painful experiment, or for the purpose of keeping them until they are killed, with a view to anatomical investigation afterwards?—They are kept for any purpose for which they are wanted; as regards guinea-pigs, mostly, almost entirely, for anatomical purposes.

2815. The question which Mr. Hutton asked you was, whether a larger number of animals are kept for painful experiment than for cure?—I have answered that question.

2816. You think that there are?—Yes. These animals are kept there as my animals, and if I have been wrong in keeping them there of course the governing body of the institution would interfere. But whether I am right or wrong my keeping them there has nothing whatever to do with the purposes of the institution.

2817. (*Mr. Hutton.*) Except that Dr. Klein, who investigates on the subject, derives his supply of animals from the same stock?—Surely that comes to the same thing. If Dr. Klein is engaged in doing work which is not part of the business of the institution, it makes no difference whether he uses them or I use them.

2818. (*Mr. Huxley.*) The fact is that keeping those animals there does not exclude a single animal from being treated?—Not the least.

2819. And, if there were any difficulty in keeping them there, there would not be the least difficulty in your keeping them somewhere else?—No.

2820. (*Chairman.*) But an officer of the institution is engaged in performing painful experiments on animals in the institution; I am speaking now of Dr. Klein's experiments?—Yes.

2821. (*Mr. Hutton.*) Will you tell me how you obtain the supply of animals for University College laboratory. We were told that at St. Bartholomew's Hospital, special directions were given as to the mode in which they were to be obtained, and were to be treated. Have you anything of the kind at University College?—We depend very much upon our servant, who is a very reliable and respectable man, and who always acts in a straightforward way in the purchase of animals. I have no precise knowledge as to the methods which are used.

2822. You do not know from where they are drawn?—I know as regards rabbits and guinea-pigs and so forth, that they are drawn from the usual sources; that they are bought in the market.

2823. I particularly refer to dogs and cats?—I cannot tell you where they come from. There is no proper provision in this country by which one can obtain dogs even for the most legitimate purposes, and of course I am not informed as to the way in which they are obtained. They are always paid for at a proper price.

2824. You do not know whether they come from the Home for Lost Dogs for instance?—I do not believe so.

2825. (*Chairman.*) I will just ask you one or two questions. You think, as I gather, that the proper organisation of physiological inquiry will diminish the number of experiments, upon the whole?—In proportion to the results to be obtained, certainly.

2826. So that if that proper organisation were to be regulated by any legislative measure, it would have the effect of excluding outsiders probably from the practice of unnecessary experiments?—I think it would, and as I said before, I would not entirely exclude outsiders.

2827. But still the tendency of it would be not to interfere with men of the greatest eminence in science, so much as to prevent unnecessary and undesirable experiments on the part of those whom I have called outsiders?—I agree to that, with the limitations which have been before made.

The witness withdrew.

Adjourned to to-morrow at twelve o'clock.

Tuesday, 26th October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

W. Rutherford M.D.

26 Oct. 1875.

WILLIAM RUTHERFORD, M.D., called in and examined.

2828. (*Chairman.*) You are Professor of the Institutes of Medicine or Physiology in the University of Edinburgh?—Yes.

2829. You have also been a teacher of physiology in King's College, London?—Yes, I have been a teacher of physiology five years in the University of Edinburgh and five years in King's College, London.

2830. The University of Edinburgh is one of the largest medical schools in the country?—Yes, it is decidedly the largest in the country.

2831. Is that science there taught by means of a course of systematic lectures?—Yes; we teach it in two ways, first of all by a course of systematic lectures, and secondly by a course of practical instruction. The practical course consists chiefly of a microscopical study of the dead tissues of the body, and very

W. Rutherford, M.D.

26 Oct. 1875.

largely too of physiological chemistry, *e.g.*, the chemistry of digestion, chemistry of the blood, and so on, and also it consists to a much smaller extent of the study of physiological apparatus, with a few experiments on living animals.

2832. Are those experiments on living animals conducted under anæsthesia?—Both in the systematic lectures and in the practical courses experiments on the higher animals, for example dogs and rabbits, are entirely conducted to the best of my knowledge devoid of pain. In the case of frogs that is generally the case but not always.

2833. (*Lord Winmarleigh.*) Devoid of pain in what manner?—Produced in the case of dogs and rabbits by opium, or chloral, or chloroform.

2834. Not simply by curari?—Not at all. The three things given for the purpose of preventing pain are opium, chloral, and chloroform. In the case of frogs, they are almost always rendered insensible.

2835. (*Mr. Hutton.*) By what?—Usually by a blow on the head.

2836. Pithed?—Yes; first of all the animal receives a blow upon the head producing instantaneous insensibility, and then the head is removed and the brain pithed. Most of the experiments on frogs are made on the nerves or muscles of the leg or the heart, after their removal from the body of an animal rendered insensible in the manner which I have just described.

3837. (*Chairman.*) In your systematic lectures are there any experiments on living animals which are not performed under complete anæsthesia?—A few in the case of frogs only. These I should say are to illustrate the action of certain poisons, for examples, strychnia and curari.

2838. What animals are used in the class of practical physiology?—A few rabbits, six at the outside, chiefly frogs, no dogs, and no cats.

2839. The rabbits being made altogether insensible to pain?—To the best of my knowledge altogether insensible to pain.

2840. How are experiments for the purpose of original research conducted?—Those are conducted either by myself, or by my assistant, or by some person acting under our immediate superintendence. Sometimes they are conducted painlessly; in other cases the animals are not insensible to pain.

2841. What is the rule by which you guide yourself in determining whether they shall be rendered insensible to pain or not?—When the mode of rendering them insensible to pain would interfere with the due result being obtained from the experiment we do not so render them.

2842. Is that any large proportion of the experiments?—I should say a considerable proportion.

2843. (*Mr. Forster.*) Would it be more than half the experiments?—I should have a difficulty in saying how many, but I should think about half the experiments that I have done.

2844. (*Mr. Hutton.*) It differs in different years I suppose?—It differs at different times.

2845. (*Chairman.*) And according to the object that you have in view?—According to the subject that you are proposing to investigate.

2846. These of which you are now speaking are only for the purpose of original research?—They are only for the purpose of original research.

2847. Now when the object in view has already been attained by former experiments at home or abroad, do you consider it justifiable to have recourse to a repetition of those experiments?—Yes, if I think it necessary in order to be persuaded of the truth of this or that fact, I consider it to be necessary to repeat the experiment that was previously performed.

2848. Has there been any great increase of the practice of vivisection in this country?—Yes, I think there has been a considerable increase of late years, owing to physiology now being taught in a more experimental manner, and also owing to the increase in the amount of physiological research which is now done, more of us devoting our entire time to the study of physiology quite detached from medical practice; on that account I think there is a considerable increase in physiological experimentation.

2849. Now you are aware I think that a great deal of feeling has been expressed in opposition to the continuation or increase of this practice?—Yes; I confess I believe that that feeling is largely founded upon misrepresentation of what is done in this country, based upon statements made with regard to what is said to be done in other countries.

2850. Do you think that there is a difference between this country and other countries in regard to the tone of feeling on this subject?—I think so.

2851. That the tone of feeling in this country is much higher than the tone of feeling in others?—Yes; I think that the English race are really upon the whole more anxious not to give pain to others than the inhabitants of some portions of the Continent. I have, I am bound to say, noticed that there is a difference in the amount of delicacy with which the human subject is treated in some hospitals abroad; and that has struck many of those who go to study medicine abroad.

2852. The higher tone of which you are now speaking as prevailing in this country is the tone of the medical practitioners in this country, and also of the students?—I think so.

2853. And that higher tone, I need scarcely ask you, you think it very desirable that we should encourage and perpetuate;—Yes; certainly.

2854. And if there were supposed to be any tendency to an approach in this country to the tone which you think has prevailed in some other places, you would regard that as a circumstance very much to be regretted?—Yes; but of course always provided that there was sufficient reason for the supposition as to its being an actual fact that there is a departure from just humanity in England. If it be a fact, then no doubt I think it requires serious consideration.

2855. Do you know whether the medical students in this country are in the habit of performing experiments in private, in their own residences, or otherwise than under the control and direction of their teachers?—I never heard of such a thing being done, neither when I was a student, nor have I heard of anything of recent years, and I am persuaded that if it were done I should be sure to have known of it.

2856. Now for the discovery of new truths, I understand you to think that experiments upon living animals of a painful nature are justifiable?—I believe so, justifiable for the discovery of new facts, and for the repetition of it may be important facts which have been recently stated. I do not know that it would be necessary for me to offer evidence with regard to the effects of discoveries in physiology upon the practice of medicine, or the advantages that have resulted from them. Perhaps indeed you may have heard abundant evidence upon that point.

2857. But you desire it to be taken as in your judgment a matter of necessity that such experiments shall occasionally take place?—Thoroughly so.

2858. Now for the education of medical students do you think it necessary?—Not except in really very exceptional circumstances. I do not think it at all necessary that any higher animal, such as a dog or a rabbit, should be subjected to pain for the education of medical students.

2859. It would be quite possible then, without any injury to science, altogether to prohibit experiments otherwise than under anæsthesia for the mere purpose of medical instruction?—In the case of higher animals; but in the case of frogs I do think that such a prohibition would somewhat interfere with tuition. For example, it is a very important thing to show the action of strychnia in producing tetanus. That is done upon a frog not anæsthetised; the animal is very soon killed by the effect of the poison; I do not think it would be judicious to have a law prohibiting our showing that to the medical student, who has to study cases of tetanus which are so rarely seen.

W. Rutherford, M.D.

26 Oct. 1875.

2860. (*Lord Winmarleigh.*) How long would the animal live under strychnia ?—Two or three minutes.

2861. Not more than that ?—No, not generally ; it depends upon the dose given ; with the dose commonly employed for showing the experiment the animal would be allowed to live three or four, or at the outside I should think five minutes.

2862. (*Chairman.*) Now do these last remarks extend to the education of physiologists ?—Yes, I think, generally ; I should say they extend to every one until he should desire to do an original research.

2863. The number of those persons whose pursuit of original research would render it necessary that they should perform painful experiments without anæsthesia, I suppose, is small ?—A very small number indeed.

2864. And the advantage to science of any large number of persons being so employed would not be considerable ?—I think not, unless they are thoroughly competent.

2865. It is, therefore, possible for the purpose of our inquiry to regard the number of persons who should perform painful experiments without anæsthesia as a very limited number ?—Certainly.

2866. And if it were known to you that any other persons besides this limited number of well qualified persons were performing such operations you would think that undesirable on the ground of humanity, and not to be commended on the ground of science ?—I do not think it should be.

2867. Where did you study physiology yourself ?—I studied it in Berlin chiefly ; I had to go there to have a whole course of experiments performed for my special benefit, not having been taught physiology experimentally in this country ; and the consequence was that there was a great expenditure of time and teaching power, and also of animals to teach me alone ; and I have always since thought that if these experiments had been shown to me when I was a student in Edinburgh the same number of animals which would have served for my teaching would have served for it might have been a hundred students.

2868. I understand you to argue upon these considerations that an organized system of public teaching would be conducive to the interests of science, and also to the interests of humanity ; is that your view ?—I think so, decidedly. I think we ought not to do away with the demonstration of certain known facts before students under certain conditions ; that physiologists ought to be permitted in their lectures to show certain experiments on animals for teaching purposes.

2869. The greater number of your experiments are upon dead tissues, I suppose ?—Yes.

2870. And a great part upon chemistry and subjects that have nothing to do with sensation ?—Yes. For example, the experiments on digestion, and those upon the changes of the blood in respiration, do not require experiments on living animals ; also those on the movement of fluids in tubes, and various experiments in vision, the accommodation of the eyes to near and distant objects, and so on, indeed, the majority, do not imply vivisection.

2871. Are you desirous of offering to the Commission any opinion as to the relative sensitiveness of animals ?—I believe that the animals that one commonly employs for experiment are not so sensitive as men ; and I infer that from this sort of reasoning : human beings differ one from another very much in their amount of sensitiveness. One man may stand a severe operation almost without wincing, while another is caused to faint or is thrown into great excitement thereby. And you may notice the same thing in the case of the lower animals ; for example, dogs ; greyhounds and spaniels are exceedingly sensitive, and are thrown into a great excitement by an operation which, if done on a sheep-dog or a mongrel dog, would scarcely produce any excitement at all ; it is wonderful what one may do to a sheep-dog without the animal making any commotion. Then there is a great difference between different species—between cats and rabbits, for instance ; a cat is a far more sensitive creature than a rabbit ; I infer that because it is thrown by similar operations into much greater commotion than the rabbit is. On that account I never perform an experiment on a cat, or a spaniel, or greyhound if I can possibly help it. I consider these the last animals I would resort to ; I always take rabbits and common dogs. Then, frogs appear to me far less sensitive than the higher animals.

2872. (*Mr. Hutton.*) May I ask you whether you think guinea pigs are sensitive ?—It would be rather difficult to say. I sometimes have thought they are not very sensitive, because sometimes they seem almost to disregard a cutting operation upon them, but on the whole I think they are tolerably sensitive animals.

2873. (*Chairman.*) I observe that in a recent publication of yours you mention Lord Henniker's Bill as having been "drawn up by the anti-vivisection party ?"—I was under that impression then.

2874. And you say that "had this Bill passed it would "have made no essential change in the conduct of the "physiological department of this University ;" is that your opinion ?—I was of that opinion when I wrote that; but on re-considering that Bill it appears to me that it might be almost a dangerous thing, at any rate an inconvenient thing I should say, for the power of granting a license to be vested in the Secretary of State. It appears to me to be difficult for that gentleman to judge whether or not a license should be granted ; that he would have to consult some person who would be likely to know, and I do not know whom he would consult. I fancy that it would be better, if such a measure be thought necessary when you have considered the real facts of the case, to vest the power of granting the license in such a body as the Councils of the Royal Societies, the Councils of the Colleges of Surgeons of London, Edinburgh, and Dublin, and the Councils of the Colleges of Physicians of London, Edinburgh, and Dublin ; and the Inspector of Anatomy might act under the jurisdiction of these councils in seeing what was carried on by the experimenters ; and these councils might in turn be responsible to the Secretary of State. It would, I believe, be extremely objectionable to make the inspector directly responsible to the State, otherwise he would virtually have the power of granting or removing licenses in his own hands, and I don't think he ought to be entrusted with such power. He ought to be simply an inspector for the licensing bodies I have mentioned.

2875. And if those arrangements suggested by you were carried into effect, you see no reason to change the opinion that the Bill would not have interfered with the practice of the University of Edinburgh ?—I do not think it would have done so had the licensing and the inspection been conducted as I have indicated.

2876. It would have interfered, if at all, then with the persons we were speaking of as a class whom it is not desirable for the interests of science to have performing these experiments ?—Certainly it would have prevented that.

2877. With regard to the other Bill which was introduced into the House of Commons by Dr. Playfair, have you considered that ?—It seems to me that that Bill was extremely objectionable.

2878. In what respect ?—Objectionable because we could not for teaching purposes, for the demonstration of known facts to our classes, have performed an experiment upon a living animal, even one that had been anæsthetised, without being liable to be fined 50*l.* and imprisoned for three months.

2879. (*Lord Winmarleigh.*) Is that so ?—Yes ; the wording of the Bill is extremely complex, but when you consider its outs and ins it comes to be so.

2880. (*Chairman.*) Supposing the Bill to bear the interpretation that you have now put upon it, it would have interfered with what you consider necessary for the instruction of your students at Edinburgh ?—It would certainly have done so, and have driven students from this country to study physiology on the Continent.

2881. But if the exhibition of such experiments to

W. Rutherford, M.D.

26 Oct. 1875.

students under complete anæsthesia had been permitted by the Bill that objection would have been entirely removed, would it not?—Not altogether, though nearly so; because there are a few experiments where a little latitude is required to be left to the teacher—a few experiments on the action of strychnia, and various things on frogs which cannot well be performed under anæsthesia, because the conditions would have been changed.

2882. But with that small amount of latitude the Bill would not have interfered with the practice of the University of Edinburgh?—No, as far as I can see at present. The wording of that Bill in many points was so complex and indefinite that I do think it would have been a very dangerous Bill. I should much have preferred Lord Henniker's Bill, if there had been legislation on the subject. I confess that if legislation were thought advisable I believe that the Government ought to license certain men to carry on vivisection, but ought to leave the details of the manner in which the vivisection is to be carried on to the persons licensed. Of course they would always remember that if they are not discreet in what they do the license will be taken from them. I think it would be very difficult to define exactly what experiments should be done under anæsthesia, and what should not.

2883. But I think you said a little while ago that you would not object to a competent inspector, and I think you instanced the present inspector of anatomy, being acquainted with everything that passes at Edinburgh?—Certainly I would not object to that, provided that his reports are to be submitted to the licensing bodies I have mentioned, and not to the Secretary of State, who could scarcely be supposed to understand all the details of this or of that case.

2884. And you would not object to a full and complete record of all that passed being kept? indeed, I suppose it is kept already?—Yes, in the published experiments.

2885. I mean you have, in your archives at Edinburgh, a record of all experiments that are performed?—Most of them; not all.

2886. You would not object to have a record of all?—I do not think that there would be any hardship in that.

2887. Then the operation of such a measure as we have now under immediate consideration could not be to interfere with the proceedings of a competent well organised school, like that of the University of Edinburgh?—I do not think it would.

2888. But it would have the effect of interfering with persons of a totally different description, if any such there be, who employ themselves in these pursuits?—Certainly.

2889. Now there has been a great deal said in some quarters about the proposed extension of the University of Edinburgh, which is now, I believe, the subject of a contract and being carried into execution?—It is so.

2890. Is it the fact that that new building is intended to be the theatre of a great development of this practice of vivisection beyond that which it has already attained in the University of Edinburgh?—Certainly not. The statement has been made by persons who are entirely ignorant of what is contemplated. We do not propose at all to increase the amount of vivisection that goes on; we simply want greater space for the carrying on of various developments of physiology—for teaching different departments; we simply want greater space because the school is so large and the students so numerous.

2891. Then if you are to carry on vivisection in a painful manner at all, I understand from you that the larger your scope and the more convenient your means the less the number of experiments that will have to be carried on; that repetitions will be rendered unnecessary, and the sufferings of the animals, on the whole, much diminished?—Yes. I should simply say that if we are permitted to perform experiments on living animals before classes for teaching purposes, the end of it would be that a smaller number of animals would be used for the repetition of known experiments, because we would do one experiment, say upon the nerves of the heart, before 200 men; they would all see it and no doubt understand the mode of experiment; whereas if 200 persons wanted to do original research upon the nerves of the heart and had not previously seen the fundamental experiment, an animal would require to be sacrificed for every one of the 200. Therefore there is a great economy of vivisection if we are permitted to teach students by vivisecting animals occasionally.

2892. The particular point I want to direct your attention to is the new building in Edinburgh; and I understand you to say that the construction of that new building will diminish the number of experiments for the reason which you have just given?—It will not diminish the number of experiments, the construction of the new building will permit of our studying physiology more easily, but about the same number of experiments will go on. At this present time we are obliged in one room, not very large, to work with the microscope, to teach chemistry, and to teach experimental physiology, that is, explaining the use of apparatus and doing experiments; but in the new building we are to have a separate room for each of these things. The size of our room, which has been called a room for experiments on animals, has been commented on as being 30 feet by 25 feet. The architect said that it was for "experiments on animals," but that means really all experiments that do not imply observations with the microscope and chemical experiments—for example, experiments on electricity, animal heat, and the motion of fluids through tubes, and so on. I think almost the smallest part of the experimental work carried on in that room, which has been called a room for the experiments on animals, would be on animals living.

2893. Then you entirely negative the impression which appears to have prevailed that the construction of this new room is to be taken as part of a determination of yours to increase and extend the practice of experiments upon living animals?—I absolutely negative it.

2894. And I understand you to say that if you have the facility of showing an experiment to a larger number of students with convenience you do in fact diminish the total number of such experiments?—Certainly.

2895. And thereby diminish the sufferings that are inflicted upon animals?—Certainly.

2896. May I take it from you then that you are of opinion that there is a different and a much more desirable tone of feeling in this country than there is in some foreign countries?—I think it is highly desirable that we should avoid the giving of unnecessary pain, but at the same time that we should have a due regard to the great importance not only of a physiological research, but also of a right method of educating our medical students.

2897. That in organized schools there are securities against abuse which do not exist in the case of private experiments?—Certainly in the case of private experiments by incompetent persons.

2898. That the tone of the medical teachers and of the students would be entirely opposed to the infliction of any unnecessary suffering?—I am sure of that. I remember that it has happened to me that a dog that I may have been showing an experiment upon has come out from its anæsthesia, and I have felt on one or two occasions that to permit it to do so is the most dangerous thing; the students at once resent it, and indicate that they desire nothing of the sort. That occurred to me some years ago, long before this furor got up, and I have since then always felt that I dare not show an experiment upon a dog or a rabbit before students when the animal was not anæsthetised.

2899. (*Lord Winmarleigh.*) Do you say that as regards London?—I say that of students in London particularly, and also in Edinburgh. I remember that my teacher, Dr. Bennett, when I was an assistant in Edinburgh, (I did not, perhaps, think so much about it

W. Rutherford, M.D.

26 Oct. 1875.

as he did, he being an older and more experienced gentleman,) would not permit of any experiment on one of the higher animals not perfectly anæsthetised, he was so afraid of the students, in addition to the fact of having his own feelings in the matter.

2900. (*Mr. Hutton.*) That applies only to the higher animals I suppose?—Yes, to dogs and other higher animals; indeed, he was so alarmed that he never had an experiment upon a dog.

2901. (*Lord Winmarleigh.*) I see that you are Professor of the Institutes of Medicine. Are all of these lectures that you give strictly connected with medicine only, or are any of them purely physiological?—I should say that the Institutes of Medicine is a term that must be taken almost simply to mean physiology. I am Professor of Physiology really; I lecture only to medical students. No doubt the medical applications of physiology are largely entered into, but it is also treated as a pure science.

2902. I see in the British Medical Journal of October the 23rd, 1875, an experiment made by you upon a dog, and the whole account of it is given there?—Yes, on the liver—on the biliary secretion of the dog.

2903. Was there any great object connected with the human frame which you had in view?—I think a very great object. Much more definite knowledge has been gained from those experiments with reference to the action of medicinal agents upon the liver than we had before.

2904. Do you think that that object would not have been obtained except through the use of a living animal?—I think certainly not; notwithstanding the great number of years that rhubarb has been given to persons there has always been a dispute whether rhubarb increases the secretion of bile or not, because rhubarb gives a colour to the stools or fœces of men somewhat like that given by an increased secretion of bile, and therefore many persons have found it impossible to say whether it increases the secretion of bile or not. It has been suspected, but not proved. Now if you put a tube in the bile duct of a dog, and measure the amount of bile secreted before and after giving rhubarb, you find that certainly the rhubarb always increases the secretion of bile; therefore we now know definitely, what was not known before, that rhubarb is a powerful stimulant of the liver.

2905. And that is a great object in medical science, is it?—Undoubtedly. And then also with reference to colchicum, which is given so much in gout; it has been suspected that colchicum was a stimulant to the liver, but it was never definitely proved until these experiments were done. We now know that colchicum is a powerful stimulant of the liver, and the information thus obtained will doubtless add greatly to the definiteness of our knowledge regarding this matter.

2906. That also you think would not have been obtained except by experiments on the living animal?—Well, such definite knowledge has not hitherto been obtained, although this medicine is daily given to the human subject.

2907. Now I observe that in this experiment, made on the occasion to which I have just referred, you used curari?—Yes.

2908. Could not that have been performed under anæsthetics?—It could not have been performed, so far as I know, under any other agent but curari, the object being to keep the animal perfectly still, because whenever an animal moves the muscles of its abdomen it squeezes out bile, and the consequence is that the flow is rendered irregular; therefore it is absolutely necessary that any movement that takes place should be a regular movement; in consequence of that; curari is given to prevent motion of the limbs—to prevent motion of the muscles of the belly; and the only compression of the liver which takes place is produced by the lungs being inflated by means of a pair of bellows at regular intervals.

2909. The fact then of curari having been applied to that dog did not then tend to diminish the pain of the experiment?—That is a point about which there is a dispute, whether curari is to be regarded as diminishing pain, or not. I believe the evidence is in favour of its producing, to some extent at all events, a state of insensibility, although I am perfectly aware that Bernard made years ago the statement that it did not. There have been experiments performed since that time which I think go far to demonstrate that it is to some extent an anæsthetic.

2910. Could you state to the Commission any circumstances which fortify your belief that curari does to a certain extent limit the pain?—I only know this, that there is an experiment on the frog introduced by Bernard, an experiment which I have shown many a time to my students, and recent experiments have been performed somewhat similarly by Mr. Yule, of Oxford, which quite corroborated experiments that I have often done and the impression that I was deducing from them, that it is to be regarded not as a substance that acts merely, as Bernard says, upon the peripheral ends of the motor nerves, but also upon the brain and the spinal cord.

2911. It has been stated by some gentleman who has given evidence here that the effect of curari was different upon different classes of animals—that it had a different effect upon the upper class of animals from that which it had upon the lower class; is that your opinion?—I am not aware of any fact which demonstrates that.

2912. Can those anæsthetics which you have spoken of, any of them, be used in such an experiment?—In some experiments opium, and chloral, and chloroform can be used in the case of the higher animals.

2913. But I understand you to say that they would have retarded your investigation in the case which you have given?—I could not have given them. It has been proved by Röhrig that the action of such a narcotic as opium diminishes the action of the liver; therefore if I had given them, and given a substance like colchicum, I might have got results upon which no definite conclusion could have been founded. It is sometimes impossible to arrive at correct therapeutic knowledge if two substances be given.

2914. You have made a comparison between medical practice in foreign countries and in England. Are you of opinion that equally beneficial results have been obtained by the more humane practice in England as in foreign countries by what you consider more cruel practices?—I was speaking of medical practice. With regard to the practices of physiologists I am bound to say that its inhumane practice has never been seen by me. I have studied in Berlin and also more recently in Leipsic, and I thought that the practice of vivisection there was exceedingly humane. I am entirely unacquainted personally with what is stated to have been done elsewhere.

2915. From your knowledge of those practices generally should you say that equal benefit has been derived by English practitioners with foreign professors?—To that I can only reply that if vivisection for teaching purposes be conducted in the humane manner which I have indicated, all the benefit that the young medical practitioners of this country require can be obtained.

2916. I understood you to say, in answer to a question put by Lord Cardwell, that you do not believe that those professing physiology with whom you are acquainted would object to some regulations being established which would secure to the public a conviction that no unnecessary cruelty was exercised in the experiments in vivisection?—I do not think that they would object to it, provided that whatever regulation is adopted the teaching of physiology be really not interfered with, and provided that the prosecution of research on the subject by competent persons be not interfered with.

2917. (*Mr. Forster.*) Take this experiment of yours of which we find a report in the last British Medical Journal. Can you tell us to what extent each of the animals would be likely to have suffered pain?—Well, I could not answer that question further than to say this—the animal I feel pursuaded would not have suffered so much pain as the human being would have

W. Rutherford, M.D.

26 Oct. 1875.

suffered under the same circumstances; I should go the length of saying, I think not nearly so much.

2918. How long was the operation ?—Usually half an hour; the after observations, which, I think, would imply scarcely any pain, lasted about eight hours in some cases; the animal was killed always at the end of the eight hours.

2919. What I understand is, that first the animal was kept fasting for 18 hours ?—Yes.

2920. I suppose that the fasting would not cause any great suffering to a dog, would it ?—I think scarcely. The animal was fed at three in the afternoon, and next morning at nine the experiment was performed, that is what is meant by the 18 hours fast.

2921. Then the actual operation would last about half an hour ?—About half an hour.

2922. In what state was the dog at the end of that half hour ?— Simply paralyzed by curari, having artificial respiration by means of a pair of bellows kept up, having a tube in its common bile duct with the bile dropping from it.

2923. And in that state it would go on for eight hours ?—Not exactly, not simply in that state; the wound in the abdominal wall being once, or twice, or sometimes three or four times, I dare say, opened, and a substance injected into the bowels, the wound was then closed again, and the animal wrapped up in cotton wadding to prevent a fall of the temperature.

2924. The animal was kept under the influence of curari the whole time ?—The whole time.

2925. Then supposing that curari does not deaden pain, would not there be very great pain during that eight hours ?—I do not think so, certainly not very great pain; I question if anything more than trivial pain.

2926. Does not the artificial respiration cause pain ?—No, I think not; it is impossible to say unless the animal can speak; but the conditions are such that you would not reasonably suppose it could cause pain, wind being blown into its chest, and distending it as in ordinary respiration.

2927. Each one of these cuttings which I see mentioned would cause pain of course ?—That is to be inferred.

2928. Did any of the dogs die during the eight hours ?—I think in one case; at this moment I can scarcely remember. A dog got very weak owing to its having got too much curari; curari paralyzes the heart if it be given in too great a dose.

2929. You consider that the curari killed the dog ?—Decidedly.

2930. Did any of the dogs cease to be under the influence of curari before they were killed ?—Not that I remember.

2931. Now with regard to the half hour of the actual operation; supposing that curari did not deaden pain, I suppose that would be a half hour of very great pain ?—It would be a half hour of pain, I should not say very great.

2932. You say that chloroform or opium could not have been administered without marring the experiment; could not ether have been administered ?—I do not think any of those could have been administered. I must tell you that I performed about 30 experiments on the same subject as that, but treated differently, some six years ago, and in every one of the operations the animal got chloroform; every dog had chloroform thoroughly given then, but not in this case, because I felt that one did not dare give the chloroform because of the risk of having the results possibly interfered with. I advisedly on this occasion in this research never gave chloroform, although I did it in every case in the previous research.

2933. The administration of curari stops any cries from the dog ?—Certainly.

2934. Then the effect is that, although it may not diminish the distress of the animal, it will diminish that distress which any operator, any spectator, must feel when an animal shows that sign of agony ?—Yes; but then I think that the evidence is distinctly in favour of its diminishing the distress felt by the animal.

2935. My reason for asking that question is, that although I feel sure, from what you have stated to be your own feeling, that this would not operate with you, I think you will admit that there might be danger that before an audience curari might be administered for painful experiments in order to prevent the students expressing their disapprobation, which you said they would do if the dog uttered cries ?—Yes; but I must state that when I do an experiment before students, for teaching purposes, I never give curari as the substance which is to prevent the animals feeling pain, because I think there is a doubt about it. I always give either opium, or chloral, or chloroform, substances about which there is no doubt, because it is not necessary to give curari alone in that case, and certainly the animal should have the benefit of the doubt.

2935a. I am not speaking of this last experiment, but there is nothing, I suppose, to prevent both chloroform and curari being given in some cases, is there ?—It is conceivable; I do not know anything to prevent it.

2936. What I mean is this—that you might give curari for the sake of the experiment in order to make the dog perfectly motionless, and that you might insure its insensibility by giving chloroform ?—You might do so. It would depend whether you would think it advisable to do so or not—upon the result that you might desire to obtain.

2937. With regard to this curari, about which we have had different evidence, because, I suppose, the facts are not positively ascertained, has there been no experience gained by the knowledge of what has happened with any human beings that have been poisoned, or slightly poisoned, by it as to whether they have suffered pain during that time or not ?—I should not like to make a statement on that matter, the reason being that I do not feel at this moment a sufficient acquaintance with all the details of the observations on human beings.

2938. (*Sir J. B. Karslake.*) Has it come to your knowledge that human beings have been poisoned by curari ?—Yes; I have read of one or two cases amongst Indians.

2939. (*Mr. Hutton.*) Claude Bernard gives experiments on human beings; you have not read the account of them, perhaps ?—I do not remember to have read anything but Bernard's account of what was seen by others in the case of Indians. But I am aware that Bernard was led by his experiments on rabbits and frogs to say that curari primarily affects the motor nerves, and he always expresses the belief that sensation is not affected. That is Bernard's statement, but I have told you that Mr. Yule's experiments warrant a different statement.

2940. (*Mr. Forster.*) You stated that you thought it was necessary to some extent to repeat experiments ?—I think it is essential in teaching.

2941. You say that it is essential in teaching ?—Essential in teaching, and essential, I should also add, in order to ascertain whether or not there is truth in an experiment which has been published.

2942. I understood you to state that, for the purposes of teaching, you would not, at any rate with dogs or with the higher animals, use painful experiments ?—No.

2943. Then, consequently, such an experiment as this recent experiment would not be used simply for the purposes of teaching ?—No.

2944. Now take it for the purposes of research; there would be a time, of course, at which you would consider that repetition was no longer necessary ?—Undoubtedly.

2945. Now can you give us any kind of impression, with regard to this particular experiment, how soon you would consider it proved so as not to require repetition ?—That must vary with the nature of the results derived from any one experiment. Take the case of the first experiment on podophylline there

W. Rutherford, M.D.

26 Oct. 1875.

given. After doing, I think, six experiments, I became convinced that it was unnecessary to repeat it any more. I do not think I should have done as many as six if some of the experiments had not yielded different results.

2946. As regards your own research, you would not, as I understand, think it necessary to try more experiments than you have tried. Now would you apply the same to other investigators, or would you consider that it was their duty also to try these experiments?—Well, I should, with regard to my experiments, think that it was not necessary for them to do so. At the same time they might adopt quite another idea, and regard it as necessary to repeat them, possibly under different conditions, and possibly with a view to saying whether this is really so, because the results are so important.

2947. I am asking this question because it seems to me that if there be any legislation to control experiments that legislation must provide that some person or persons should give an opinion as to when a repetition was, or was not, to be considered permissible?—I think you would involve the whole subject in endless difficulty unless you left it to the discretion of the person licensed that he should do this or that.

2948. But then is not that really not only leaving it to the discretion of the person, and therefore to his knowledge, but making the matter depend upon his sensibility with regard to these matters, which certainly, as between England and foreign countries, very considerably varies, and might possibly vary in England itself?—No doubt it would; but it would be exceedingly difficult for any legislative authority I think to decide as to when it would be necessary to do this or that, to repeat this or that. I do not see how it could be done without really stopping physiological research.

2949. You do not object I think to a record being kept of experiments?—I should not object to that.

2950. Both as regards the quantity of the animals, and the object of the experiment, and the description of the experiment?—Yes, I do not think there would be anything objectionable in that, because it is as you see all detailed and published there.

2951. You stated that you saw no objection to an inspector having access to experiments, and you mentioned that you personally would not object to the Inspector of Anatomy at Edinburgh?—I would not object to that provided that there is to be legislation.

2952. Is that inspector a medical man?—He is a medical man.

2953. I am not giving any opinion myself, but I may mention that some witnesses say that they do not consider that either the licensing or the inspection ought to be entirely in the hands of the medical profession, because, they say, to put it in very short language, that they might be led away by their objects, and by their commendable enthusiasm in their objects, and require to be checked by some layman. Do you think that the truth of that opinion is not to be admitted?—I feel convinced that the medical profession are men as humane as laymen; indeed their whole vocation is to relieve pain. I confess I think that we are anticipating matters a good deal. I feel persuaded from my own knowledge that there are not those abuses carried on by the medical profession that have been stated. I confess I think it is altogether a misrepresentation, and we are anticipating matters. Why not suppose a great many things that it would require legislative enactment to prevent? But that would be meddlesome legislation unless there actually are abuses to be corrected.

2954. Would you consider that in those countries in which they do occur or may occur, they are owing rather to the general tone in those countries in regard to the treatment of animals than to any especial carelessness about animal pain on the part of the medical profession?—As I have had no personal experience regarding alleged cruelties in vivisection on any part of the Continent, I would rather offer no opinion.

2955. As regards this experiment in the Medical Journal, would you kindly tell me again what, so far as rhubarb was concerned, was the object and likely to be the practical result of this experiment?—The object was simply to ascertain whether or not rhubarb does excite the liver.

2956. Will you kindly tell me what is the practical advantage in medicine of ascertaining that fact?—I will suppose a case. If a man have a gall stone in his common bile duct, obstruction is offered to the exit of the bile. It passes into the lymph vessels, thence into the circulation, and poisons the system. The gall stone usually finds its way slowly down the duct, passes into the bowel, and is thus got rid of. Owing to the interruption to the exit of the bile, the liver appears to become sluggish, and it is of great importance to know definitely what agents really do excite the liver to increased action, so that its normal activity may be restored as soon as possible, and thus hasten recovery from the jaundiced state. Moreover, it is quite conceivable that when all pain resulting from distention of the bile duct by the gall stone has subsided, and the stone just about to pass into the bowel, that by exciting the liver and increasing the pressure of the bile behind the gall stone its removal might be to some extent facilitated.

2957. As regards rhubarb, has it been the habit of the profession to give it for that purpose?—There have been various statements, some believing that it has the effect which I state, and others that it has not. When I did these experiments I said, "I have been trying rhubarb and a number of other things," and a medical practitioner said to me, "Oh! but rhubarb has no effect on the liver; it is all nonsense."

2958. Would the practical result then be that in the case of having to treat a patient with the gall stone you would give rhubarb?—It would be a very sensible treatment in the latter stage of the jaundice that I have mentioned, to give rhubarb or perhaps podophylline.

2959. My reason for asking this question is, that I could understand that you might obtain by this experiment this amount of knowledge, that rhubarb would have some effect in increasing the flow of the bile; but unless you ascertained that rhubarb would have considerable effect, all that you seem to me to get at by these painful experiments is, that something does a little, but not enough to be of any practical use in medicine?—I must remind you that the medicine can never be perfectly exact. We may by our experiments remove the hitherto existing doubt as to whether or not rhubarb really does excite the liver. To remove that doubt is a great step, but we shall never be able to say that in two different individuals with livers in states of torpidity from different causes that the same dose of rhubarb or of podophylline will produce the same amount of effect, or even whether in any case they will produce the same marked effect that they do in dogs. Apart from gall stones altogether, the liver is apt to become sluggish in many cases; and although these experiments on dogs cannot tell us what effect or what amount of effect will follow when the medicine is given to man, it is a great step to know that even in the dog rhubarb never fails to excite the liver, and that colchicum and other substances also do so. The great approbrium of medicine at this moment is the indefiniteness of our knowledge regarding the actions of medicines. It is now evident to all that the proper way to diminish this ignorance is for the physiologist to perform such experiments as these on the lower animals, and then to submit his results to medical practitioners, so that they may obtain therefrom suggestions regarding the employment of these medicines on man.

2960. Then I am to understand that from that knowledge of physiology you say that the facts you obtained from these experiments are not only of importance as increasing the general range of knowledge, (and I do not dispute that that is important, because I know that inferences may be drawn from it,) but that they are of practical advantage in the actual practice

W. Rutherford, M.D.

26 Oct. 1875.

of the medical profession?—Yes, they are calculated to prolong human life and diminish human suffering.

2961. (*Sir J. B. Karslake.*) As I understand you, in the experiment which has been referred to, you consider that you have established the fact that the action of rhubarb upon the liver is to increase the flow of bile?—Yes, in the case of the dog.

2962. Supposing the case of the dog and the case of the human being to be analogous, then, as I understand you, you say that you leave it to the medical men to determine whether they will use that rhubarb which you have shown has the effect, in the case of the dog, of affecting the flow of the bile in the liver?—Yes. I show the fact on the dog, leaving it to others to experiment on man.

2963. And as I understand you, in the instance which you gave of the gall stone, what you anticipate would be the effect would be that the mechanical action of the increased flow of bile might discharge it also?—It would probably facilitate the passage of the gall stone into the intestines.

2964. In the case of colchicum, which you have also spoken of, you have established, you say, in your judgment, that colchicum administered to a dog increases the flow of bile in the liver?—Yes.

2965. And again you leave it to the medical man to determine whether, you having told him that, he will apply it to the human subject?—Yes. It has been suspected to have this action upon the liver in man, but has never been definitely proved to have it. The fact that it does produce this action in the case of the dog strengthens the belief that it does so also in man.

2966. Passing to another question, in your judgment and your own experience, are operations of that description upon the dog to be taken as being evidence of what the effect would be on the human being?—Certainly not, but merely as suggesting what the action would be; that is all. The experiment must also be tried upon man before a conclusion can be drawn.

2967. Supposing it has been stated that in the case of colchicum, or some other drug, the operation upon man would be so different from what it would be on the dog that it would be useless to try the effect of using it on the dog for the purpose of ascertaining what the effect would be on man, what would you say?—That is hypothetical. No conclusion can be drawn until the experiment is tried.

2968. Now with reference to your own education, as I understand you, having gone through the education which you could acquire in England, you found it necessary to go to Berlin for the purpose of perfecting that education in regard to physiological research?—Yes; and also for the purpose of getting to know really something more about the mechanism of the body, in order to comprehend diseased conditions better.

2969. May I ask you how many years ago it was, about, that you studied at Berlin?—It is eleven years ago.

2970. At that time were there any means by which you could acquire the knowledge which you desired in England or in Scotland, and which you did acquire at Berlin?—No.

2971. Do you think it was essential in order to complete your education that you should see that series of experiments which you witnessed at Berlin?—Yes, both for the purpose of becoming a physiologist, and also in order to have a more perfect education as a medical man.

2972. You think that for both purposes it was necessary?—Decidedly.

2273. And you could not acquire that knowledge in this country which you acquired at Berlin?—No, not at that time; but I could now.

2974. Then, how lately was it that you went to Leipsic for the purpose of seeing further experiments?—Five years ago.

2975. Could you have witnessed those experiments in this country at that time?—No. I did not see the whole range of experiments when I was in Berlin; and in Edinburgh when I became a teacher of physiology I had to really educate myself to a large extent, and I went to Leipsic to see further modes of experimenting, which I had not the opportunity of seeing in this country.

2976. Now you have told us to what extent as a teacher you demonstrate by experiments on animals certain matters which you consider as essential for the students to understand?—Yes.

2977. Do you think that the students under your charge would be sufficiently and duly educated without witnessing those experiments?—Certainly not.

2978. Let me take one instance that you gave us more than once, that of showing to the students who are under your charge the effect of strychnine; did you administer that to a frog?—I gave it to a frog.

2979. In your opinion is it essential for a student not only to know from reading what the effect of strychnine is but also to see its effects?—I think it is a great advantage for him to see the effect, so that he may recognise it in the human subject in the case of poisoning by strychnine at once, and moreover to have a right comprehension of what is meant by a state of tetanus, and to have it demonstrated to him by a series of experimental steps that tetanus from strychnia is not due to direct action of the poison on the muscles or nerve trunk, but upon the spinal cord. Not only does the student learn this in the case of strychnia, but he also learns the mode of investigating the action of any new substance which may act like strychnia.

2980. A gentleman who has been examined as a witness before the Commission says, as I understand him, that there is nothing which you could learn from seeing an animal under the influence of strychnine that you could not learn from reading a description of the effect of strychnine upon an animal. Is that your opinion?—I thoroughly disagree with that statement. I am convinced that in many matters it is impossible from reading to gain such an idea of a subject, or of a fact, as can be obtained from seeing the thing; the impression produced upon the mind is so much more vivid, and the impression is so much more true. I believe it is not possible in many facts of physiology for a student to get a sufficient idea of the matter from books. For example, in experiments on the heart, there is a nerve which when stimulated retards the heart's action. There is a poison, belladonna, which when given, prevents the action of that nerve upon the heart. The student could not apprehend these matters so fully and be so thoroughly impressed by them by reading as by seeing.

2981. Is it in the belief then that it is essential that the student should see the operation of those poisons upon animals that you find it necessary, or that you think it necessary, in the course of your instruction, to show those experiments to them?—Yes. But let me say that showing the action of poisons is certainly the least part of the whole. It is essential to see the action of a few poisons on animals, but it is more essential that they should see a number of other experiments on animals, in order that they may comprehend the mechanism of the body.

2982. And is it in that belief that the experiments that you introduce are shown to the students under your charge?—Only so.

2983. (*Mr. Hutton.*) From what you say I take it that the question of whether or not an experiment is desirable for demonstrative purposes is very much a matter of opinion among physiologists. Can you tell us whether there is any great difference in that respect between the German schools and the English?—I do not know that there is any difference now in the matter of opinion as to whether or not it is desirable to have such experiments for demonstrative purposes.

2984. I mean to say as to the number of painful experiments?—I think there is a difference of opinion. I believe in this country we are more careful about repeating a painful experiment.

2985. You seem to think that the German schools are on the whole very moderate in that respect?—The

W. Rutherford, M.D.

26 Oct. 1875.

German schools which I visited appeared to me to be moderate.

2986. But still they would go further than the English?—Well, I think rather further than I should go for the tuition of medical students.

2987. In Berlin and Leipsic did you see demonstrative experiments of a more painful kind than you would show in your own school?—In Berlin I did, but these experiments were shown to me as a person desirous of becoming a physiologist.

2988. Then if this school of physiological experiments extends to England, it is more or less likely that men of that way of thinking might grow up in England also; it is a matter of opinion?—No doubt it is a matter of opinion.

2989. It is simply, I suppose, that the Germans are as tender to pain generally as the English, and that in the zeal of science in Germany they do as a matter of fact find it necessary to show more experiments than we do?—I must decline to make any comparisons between the Germans and the English, because, although my physiological friends in Germany showed me some experiments which I do not think it necessary to repeat merely for the tuition of medical students, they showed me these experiments at my own request, and I thank them heartily for the gain to my knowledge. I really have had no personal experience of any unnecessary or reckless vivisection on any part of the Continent.

2990. Now can you give me any impression at all of what you might call the consumption of living animals for all purposes, research and otherwise, in your laboratory in Edinburgh?—That there is so much I can tell you for teaching purposes.

2991. For teaching purposes I think you have already published the numbers, have you not?—Yes; but as to research the number must vary with the research. For teaching purposes in systematic lectures I use two dogs, three rabbits, and a considerable number of frogs in the course of the year. In the class of practical physiology, in the course of a year I use not more I think than six rabbits, and a considerable number of frogs, that is for teaching purposes.

2992. (*Sir J. B. Karslake.*) And nothing else?—I should say we may use guinea pigs; I really have never used guinea pigs, but they might be used. I do not use them for teaching purposes; that is all that I use for teaching purposes.

2993. (*Mr. Hutton.*) Then for purposes of research how many animals do you use?—For purposes of research the number of animals used varies with the research that may be undertaken. Last year for purposes of research I think I used about 40 dogs perhaps, and of rabbits, at the very outside, eight.

2994. (*Mr. Forster.*) Did you use any cats?—No cats, and no guinea pigs. I should say further that that number of dogs is quite an exceptional thing.

2995. (*Mr. Hutton.*) That was the largest that you have ever used?—Yes; during the whole five years that I was in London, for the purposes of research, I am sure I did not use more than 10 dogs; this is quite an exceptional thing.

2996. Then I think that in a published letter of yours you state that you occasionally allow students to operate under your direction?—I did not state so.

2997. That is so reported, is it not?—I said that they might be permitted; they never are for original research. Let me state exactly what students do in Edinburgh. They perform no experiment upon a living animal, excepting that of demonstrating the circulation of the blood under the microscope. If any student desired to undertake an original research I should allow him to do so under my superintendence, provided that I were persuaded that he was competent to perform the necessary operations, and that the subject was worth it. Such a case has never occurred during my ten years experience.

2998. Now can you give me the least impression as to the yearly consumption at a great laboratory like Ludwig's, at Leipsic, of living animals?—I cannot, because I was only there one month.

2999. Can you supply that information as regards Berlin?—No; I only attended one lecture by Dubois Reymond; I had simply a private course of instruction in the laboratory. The number in Berlin is not large, because they have not done much experimentation on animals.

3000. It might be taken to be very much larger than the English, I suppose?—I am quite unable to offer any opinion.

3001. You say that you have noticed a considerable difference in the treatment of human patients abroad as compared with their treatment in this country in hospitals—more disposition to experiment on them, I suppose you mean?—No, not at all.

3002. I understood you to say that you had noticed a difference in the treatment?—I noticed that there was less delicacy in the treatment of human beings in some parts of the Continent that I visited, but I hope I am not to be asked to say where.

3003. Do you not connect that in any degree with the deadening practice of constantly operating on living animals?—Certainly not.

3004. You think it is a matter purely of national temperament?—Purely.

3005. Do you think there would be any practical inconvenience in excluding what we may call the domestic animals altogether from these experiments—dogs, cats, and horses?—I think it would be distinctly not only inconvenient—but it would be a great blow to the teaching of medicine and physiology in this country.

3006. In what way?—Because the students would not be educated as they ought to be—not so well as they can be.

3007. Why could you not show the same experiments on animals that are not domestic animals?—You cannot possibly. For example, if you want to measure the pressure of the blood, it is scarcely at all to be done in a frog; the animal to take is a dog or a rabbit.

3008. Or a guinea pig?—A guinea pig one never takes for this purpose. A student will not gain a sufficient idea of what is meant by the blood pressure in the human subject unless you take an animal which in some measure represents man; not a frog of course, but a dog or a rabbit. We never take a horse.

3009. A very eminent man tells me that he should like to give evidence that experiments in arterial pressure are entirely unnecessary before a class—that they might be given through hydraulic machinery, which would show exactly the same; is that your opinion?—Certainly not, it would not show exactly the same. But by all means let the eminent man give his evidence.

3010. Where you speak of chloral and opium, those I suppose have not at all the same effect as chloroform; they are simply naraotics; they stupefy, but do not take away pain; they diminish the sense of pain, but do not destroy it; is not that so?—I do not know why you should suppose so, because the evidence is so exactly the opposite.

3011. You think that opium and chloral destroy pain as much as chloroform, do you?—Yes, if you give them in sufficient doses.

3012. Now I understood you to say that the action of the drugs on which you had experimented might be very different on dogs from that on man. Is it not true that it is very different as regards calomel?—I should not say it is true that it is very different; I do not know who has proved that to be true. I say that is a question open for consideration.

3013. I thought it had been demonstrated to be so?—That is a question much disputed.

3014. But you have not come to any conclusion yourself on the subject?—No; because I have not performed the experiments on man.

3015. But were not the differences between you and your predecessor, as regards the results of those experiments, considerable, although you explained them, I believe, by the fact that your experiments

W. Rutherford, M.D.

26 Oct. 1875.

were on fasting animals and his on non-fasting animals ?—Yes, the conclusions drawn regarding podophylline were different.

3016. Does not that suggest that the same experiment must be repeated to see whether that was the cause of the difference ?—It might be; I do not know that it would be necessary, but still it might be.

3017. My point is, that on the whole the results are purely approximate, and may be subsequently disputed ?—Well, I could conceive that they might be disputed, although I do not think that there is any reasonable ground for disputing them.

3018. I understand you to say (and that is a point on which I am rather anxious to get a distinct answer) that you find dogs and cats so very much more useful than other animals for the purposes of experiments that it would be destroying your practical physiology to exclude them ?—I said dogs and rabbits are required in addition to frogs; I am distinctly of that opinion.

3019. The rabbit, I take it, is not a domestic animal; would not rabbits alone be sufficient for your purposes? I believe they are less sensitive, are they not, than most other animals ?—I do not think that rabbits alone would suffice; I think it is necessary to have my two dogs.

3020. Would not your experiments on podophylline and other substances have succeeded equally well if tried on rabbits ?—My very first experiment with podophylline was tried on a rabbit, and I got no result; I tried it on a dog and got a result similar to what is supposed to take place in man.

3021. Is it not conceivable that somebody might say that the results were spoiled by your use of curari ?—Quite conceivable, but not likely, because I give sufficient reason for stating that it is not likely in the report.

The witness withdrew.

Mr. William Turner, M.B., called in and examined.

Mr. W. Turner, M.B.

3022. (*Chairman.*) You are Professor of Anatomy in the University of Edinburgh ?—I am.

3023. In that capacity do you yourself come into connexion with the subject of experiments upon living animals ?—I do not myself for class purposes, for demonstration purposes, experiment on living animals; my work as a teacher lies with dead bodies, not with living animals.

3024. Have you given much consideration to the subject which is referred to us ?—I have.

3025. Will you state what is the result of that consideration ?—I have made a few jottings to assist me in what I have to say on this matter, and I propose in the first instance to speak of the practice of submitting living animals to experiments for scientific purposes in its bearings on the advancement of physiological science generally. With this object I have made notes of the history of various discoveries, and I propose to take in illustration the discovery of the circulation of the blood, the discovery of the lacteal and lymphatic system of vessels, and the discovery of the compound function of the spinal nerves; and I have selected these three subjects for illustration because they lie at the very foundation of all our present physiological knowledge; without them physiology, and consequently practical medicine, would be a perfect chaos; and moreover, the history of the discovery of these matters is so well ascertained and so generally accepted that I do not think that any exception can be taken to the narrative which I shall give. With regard to the discovery of the circulation of the blood, this, as the Commission of course know, was made by the immortal Harvey, our own countryman, who published his memoir on the motion of the heart and of the blood in the year 1628. Before the time of Harvey many important observations had been made by anatomists, and many facts discovered. The structure of the heart, the difference between the arteries and the veins, the presence of valves in the veins, were all known; and these were discoveries which were necessary as a preliminary to the discovery of the circulation of the blood itself. These discoveries were all anatomical, made by observation on dead bodies; but in order that the discovery of the circulation of the blood should be made, it was necessary that the living body should be examined; and I may select one or two passages from the memoir of Harvey, to which I have just referred, so that the Commission may have before them Harvey's own testimony on this matter. In the first chapter of his memoir, as rendered by his translator Dr. Willis, I find the following statement: "When I first gave my mind to vivisections, as a means of discovering the motions and uses of the heart, and sought to discover these from actual inspection and not from the writings of others, I found the task so truly arduous, so full of difficulties, that I was almost tempted to think, with Fracastorius, that the motion of the heart was only to be comprehended by God. For I could neither rightly perceive at first when the systole and when the diastole took place, nor when and where dilatation and contraction occurred, by reason of the rapidity of the motion, which in many animals is accomplished in the twinkling of an eye, coming and going like a flash of lightning; so that the systole presented itself to me now from this point, now from that, the diastole the same; and then everything was reversed, the motions occurring, as it seemed, variously and confusedly together. My mind was, therefore, greatly unsettled, nor did I know what I should myself conclude, nor what believe from others. I was not surprised that Andreas Laurentius should have said that the motion of the heart was as perplexing as the flux and reflux of Euripus had appeared to Aristotle. At length, and by using greater and daily diligence, having frequent recourse to vivisections, employing a variety of animals for the purpose, and collating numerous observations, I thought that I had attained to the truth, that I should extricate myself and escape from this labyrinth, and that I had discovered what I so much desired, both the motion and the use of the heart and arteries, since which time I have not hesitated to expose my views upon these subjects, not only in private to my friends but also in public in my anatomical lectures, after the manner of the Academy of old." Then in the second chapter of the same treatise is a passage which refers to the same subject, and states what the animals are on which he made his observations. These statements are as follows: "These things are more obvious in the colder animals, such as toads, frogs, serpents, small fishes, crabs, shrimps, snails, and shell fish. They also become more distinct in warm-blooded animals, such as the dog and hog, if they be attentively noted when the heart begins to flag, to move more slowly, and, as it were, to die; the movements then become slower and rarer, the pauses longer, by which it is made much more easy to perceive and unravel what the motions really are, and how they are performed. In the pause, as in death, the heart is soft, flaccid, exhausted, lying, as it were, at rest." In the sixth chapter of the same treatise there are also observations bearing on the same matter, and showing how errors had arisen through the non-employment of vivisection by previous observers. He says, "Since the intimate connexion of the heart with the lungs, which is apparent in the human subject, has been the probable cause of the errors that have been committed on this point, they plainly do amiss who, pretending to speak of the parts of animals generally, as anatomists for the most part do, confine their researches to the

Mr.
W. Turner,
M.B.

26 Oct. 1875.

"human body alone, and that when it is dead. They obviously act no otherwise than he who, having studied the forms of a single commonwealth, should set about the composition of a general system of polity; or who, having taken cognizance of the nature of a single field, should imagine that he had mastered the science of agriculture; or who, upon the ground of one particular proposition, should proceed to draw general conclusions." Then it may be a matter perhaps of some interest to the Commission to know that when Harvey had published his very important treatise, objections were raised to his results on the ground that he had got at them by practising vivisection—so that in his time, as in the present day, objections were made to the use of this method of inquiry as an aid to physiological discovery; and it may be interesting, perhaps, just to read a passage from his letter to Riolanus, who was a noted anatomist of the period: "There are some, too, who say that I have shown a vain-glorious love of vivisections, and who scoff at and deride the introduction of frogs and serpents, flies, and others of the lower animals upon the scene, as a piece of puerile levity, not even refraining from opprobrious epithets. To return evil speaking with evil speaking, however, I hold to be unworthy in a philosopher and searcher after truth; I believe that I shall do better and more advisedly if I meet so many indications of ill-breeding with the light of faithful and conclusive observation." These observations of Harvey are those by which the circulation of the blood was established. But there was one link yet wanting in the chain. That link could not be supplied by Harvey because in his day the means of observation were not at his disposal. It was, however, supplied in 1661 by the Italian anatomist, Malpighi, who by observations with the microscope made upon the lungs of a living frog saw the passage of the blood from the arteries into the veins through the capillaries; and thus, by observations on a living animal, completed the discovery. The next illustration that I wish to bring forward is the discovery of the important system of vessels known as the lacteal vessels, or the lymphatic vessels, vessels which are intimately concerned in the absorption of the food and in the process of nutrition. In short, the observations and discoveries on these vessels lie at the very root of all our knowledge of digestion and the assimilation of the food. The first observation on the discovery of the lacteal vessels was made by the Italian anatomist Asellius in the year 1622. I may explain that these vessels are of a very remarkable character; they are, as a rule, extremely minute; their coats are so transparent that they cannot be seen excepting when they are filled; they must be filled either with the chyle which they convey from the bowels, or by some artificial means. The best means of seeing them is when they are filled with their natural fluid, that is the chyle; and their chyle contents are only to be seen at the time when digestion is going on. After the food has passed away from the bowels the chyle is no longer in these vessels; they must be seen, therefore, when digestion is going on. Now Asellius discovered these vessels by opening the body of a living dog at the time when it was digesting food; and then they became a subject of frequent demonstration after that period. But although Asellius discovered them he did not entirely comprehend what their direction and course was. He supposed that they ended in the liver. It was reserved for the French anatomist, Pecquet, in 1649, to determine that these vessels terminated in the great veins at the root of the neck, and that the chyle or absorbed material of the food was poured into the venous system to mix with the blood, and so flow onwards in the course of the circulation and be applied to nutritive purposes. This observation of Pecquet's was also made on a living animal, and he determined the passage of the chyle along the thoracic duct by tying it and observing that the chyle flowed up to the seat of ligature, and that then the vessel became distended immediately behind the seat of ligature. The attention of anatomists and physiologists having been directed to these vessels, they have been experimented on and observed with great care since that period, and even now the attention of two very eminent physiologists in this metropolis, Dr. Burdon Sanderson and Dr. Klein, is being directed to these lymphatic vessels, and there is every reason to believe that the observations and experiments which they are making on this system of vessels will tend in the most material manner to the advancement of medical practice, as well as of physiological science. The third illustration that I have selected is the discovery of the compound function of the spinal nerves. Here again anatomy had led to a certain amount of knowledge. It was known that each spinal nerve arises by two roots; but until the beginning of the present century no one had supposed that these roots of the spinal nerves had different functions. An Edinburgh anatomist, Mr. Alexander Walker, published in 1809 certain speculations on the roots of these nerves, which were based entirely on anatomical observation without the use of experiments. He supposed that the anterior roots of the nerves were concerned in sensibility, and that the posterior roots were concerned in volition. If Mr. Walker had resorted to experiments he would soon have satisfied himself that, although he was quite right in the supposition that the roots of the nerves had different functions, he had made a most important error in ascribing to the anterior root sensibility and to the posterior root volition. At the same time that Mr. Walker was speculating on these questions, Sir Charles Bell, then Mr. Charles Bell, was considering the matter; and from extracts from some of his letters which have been published it appears that in the years 1807, 1808, and 1809 he had been pondering in his mind the functions of the nerves. I may quote a sentence from a letter of his dated the 4th of December 1809, written to his brother, in which he says "I shall be very bloody in this brain of mine," (that is in the researches which he was contemplating,) "I must make experiments, and that is what I hate to do." Then in a letter, dated the 2nd of March 1810, he says: "It occurred to me that, as there were four grand divisions of the brain, so were there four divisions of the spinal marrow; first, a lateral division, then a division into the back and forepart. Next, it occurred to me that all the spinal nerves had within the sheath of the spinal marrow two roots, one from the back part, another from before. Whenever this occurred to me I thought that I had obtained a method of inquiring into the function of the parts of the brain. Exp. I.—I opened the spine, and pricked and injured the posterior filaments of the nerves; no motion of the muscles followed. I then touched the anterior division; immediately the parts were convulsed. Exp. II.—I now destroyed the posterior part of the spinal marrow by the point of a needle; no convulsive movement followed; I injured the anterior part, and the animal was convulsed." In these experiments, Sir Charles Bell made certain discoveries; he showed that the anterior root, instead of being, as Walker supposed, concerned in sensibility, was really concerned in influencing the movements of the muscles because the parts were convulsed when the root was pricked. But Sir Charles Bell failed at that time to discover what the function of the posterior root of the spinal nerve was. It required many more experiments both on his part and also on the part of the French physiologist Majendie to determine precisely, as we now understand them, the relative functions of the two roots of the spinal nerve.

The second head into which I had arranged my observations was with reference to the influence exercised by experiments on living animals in making improvements in the art of healing, the medical art. And in the first place I propose to direct attention to the experiments of Dr. Jones made in the beginning of the present century as regards the suppression of hæmorrhage from divided arteries, and also as regards

Mr. W. Turner, M.B.

26 Oct. 1875.

the use of the ligature. With regard to these experiments I might perhaps be allowed to make one or two quotations from the writings of eminent surgeons as to their great importance; and I would first read a passage from an essay written by the late Sir William Lawrence, who was eminent not only as a practical surgeon, but also for his knowledge of all matters connected with the literature of surgery. He says, speaking of Dr. Jones, "He has banished the use of thick and "broad threads, of tapes, of reserve ligatures, of cylin-"ders of cork and wood, linen compresses, and all the "contrivances which, employed as a security against "bleeding, only served to multiply the chances of its "occurrence." The late Mr. Samuel Cooper, who was also an eminent surgeon and the author of an important work on surgery, says, "The principles "which should guide the surgeon in the use of the "ligature were not known until the late Dr. Jones "published his valuable treatise on hæmorrhage." And a living surgeon, Professor Spence, one of my colleagues in the University of Edinburgh, who is entitled to speak authoritatively as to the value of Dr. Jones's experiments because he himself has performed many experiments in the same direction, says, "When we look at the principles laid down by Dr. "Jones as the results of his investigations, and for "which he has received so much credit, it will be "found that the great service he performed consisted "not so much in pointing out any new fact observed "in the process of obliteration of an artery as in scien-"tifically investigating the subject as a whole, ascer-"taining in a great measure the relative value of the "different parts of the process, and drawing from his "experiments sound practical deductions as to the "causes of secondary hæmorrhage, and as to the best "means of procuring obliteration." From the opinion of these distinguished surgeons, as well as from the fact that the principles which Dr. Jones advocated, are daily applied in practice, I think there can be no question that his experiments have exercised a great influence on the improvement of the healing art. With reference to his experiments Dr. Jones, in the preface to his book, makes some observations which may perhaps be interesting to the Commission. He says, "He has only a "few words more to say, addressed to men out of the "pale of his profession into whose hands this little "book may fall, whose opinions he esteems, and "whose feelings he honours. He regrets the necessity "of obtaining even this important knowledge by the "sacrifice of brutes. But when we remember the "incessant scourge of war which has followed man "through all the ages of his history—not to mention "the consequences of accident and disease—it is not "too much to assert that thousands might have been, "and may still be, saved by a perfect knowledge of "these subjects; which can only be directly obtained "by experiments on brutes; indirectly, and very "slowly, by observations on the injured arteries of "man; and even these cannot be made until he has "fallen a sacrifice to the want of assistance, or to the "imperfect knowledge of the surgeon."

3026. (*Mr. Forster.*) What was the date of that?—This book of Dr. Jones's was published in 1805.

3027. (*Mr. Erichsen.*) He made his experiments chiefly on horses, I think?—Horses, asses, and dogs. The experiments also made by John Hunter on the arteries of dogs, with reference to the treatment of the serious disease of the arteries called aneurism, have been of great value in guiding surgeons to the best mode of treating this disease. The experiments of Drs. Hope and Williams are of importance in determining the cause of the sounds of the heart, and in enabling the practical physician to diagnose certain of the diseases of that important organ. Then the important experiments which were made by Dr. Jenner in connexion with the subject of vaccination may also be referred to. It is well known that the discovery of vaccination was made by Dr. Jenner from observations on cows, and those who milked cows, in the dairy county of Gloucester. He observed that cows had occasionally a pustular eruption on the udder, that those who milked cows so affected, contracted pustules on their hands, and that such persons enjoyed an immunity from small-pox. From these observations he proceeded to investigate carefully the whole subject, and established the practice of vaccination which has been of such enormous importance to humanity. But Jenner's observations were not limited to cows, for there was another step in the process, namely, the prior communication from the horse to the cow of matter, which occasioned in the cow the pustular eruption. Jenner observed that those cows which had their udders affected had been milked by persons who had been tending horses having an affection of the hoof, called grease of the hoof. The farm servants who attended on these horses went and milked the cows, and in this manner from the horse to the cow matter was communicated which led to the production of pustules on the udders of the cows. This is brought out not only in Jenner's original memoirs on vaccination, but also in the Life of Jenner compiled by his biographer Dr. Baron. Jenner himself, in order to establish a complete history of the transference of this matter, was desirous of inoculating a cow from a horse, but it so happened that, as he states in a letter which is quoted by Dr. Baron, he could not procure a horse at the time which had the grease in its heels, so that he himself was not able to carry out the experiments, although he was strongly urged to do it by various of his friends. But so important was it considered that those experiments should be carried out, that it was done by another observer, a Mr. Tanner, and Dr. Baron states: "Mr. Tanner had the merit of "proving the truth of this doctrine; he succeeded in "communicating the disease to the cow by inserting "some liquid matter taken from the heel of the horse. "This produced on the teat of the cow a complete "vaccine pustule." The whole history of the discovery of vaccination, a discovery which is second to no other in the benefits it has conferred on the human race, proves that it is based on experiments on living animals, the full meaning of which was interpreted by the acute and philosophic mind of Jenner. Then lastly I would refer to the experiments performed by the Italian physician Galvani in the year 1786. These experiments are of enormous importance in their results, not merely in their bearings on the science of physiology, on the medical art and its improvement, but upon the arts generally and upon the comforts and welfare of mankind. The experiment of Galvani's which is of importance in connexion with this matter was one performed in the course of a series of researches which he was carrying out on frogs relative to the determination of animal electricity. He found that by applying a plate of silver and a plate of copper to the nerves and the muscles of a frog he excited contraction of the muscles of the frog. Now that experiment, simple though it may appear, is the fundamental experiment which has led through the researches of Volta, Davy, Faraday, Œrsted, Thomson, and others, to all that we know about current electricity, about electro-magnetism, and about magnetic electricity, with all their applications to therapeutics, to electric telegraphy, to electro-plating, and to lighthouse electricity. All these most important applications take their origin from this experiment of Galvani's on a frog. Such were some of the observations which I had thought of in connexion with this subject.

3028. (*Chairman.*) You have adduced these various cases for the purpose of showing generally what you consider to be the necessity of occasional recurrence to experiments upon living animals?—I have.

3029. Now coming down to the present time and to our practice, are the majority of experiments capable of being performed under the newly discovered anæsthetics, or some of them?—A large proportion of experiments may be performed either on animals that are anæsthetised or on animals that have had their heads cut off, and that no longer have sensation.

3030. For the purposes of demonstration to students, do you consider experiments on living animals to be

Mr. W. Turner, M.B.

26 Oct. 1875.

necessary?—In some cases they may be, but I am by no means an advocate for the indiscriminate performance of experiments before students; I think it should be limited.

3031. You think that the use of experiments on living animals at all for purposes of demonstration to students should be very limited?—I think so.

3032. If limited to experiments performed always under complete anæsthesia, would that be the sort of limitation to which you would point?—It is possible that experiments might have to be performed on animals not under the influence of anæsthesia, but I should say speaking generally that the great majority of them might be performed under its influence.

3033. Speaking generally, experiments for the purpose of demonstration to students may quite well be performed under anæsthetics?—Speaking generally.

3034. Now with regard to experiments for original research, may the greatest number of them be performed under anæsthetics?—I believe so.

3035. And of those that cannot be performed altogether under anæsthetics, may a large part be so performed that the most painful part of the operation is under anæsthetics?—I believe so.

3036. Leaving, therefore, only a limited portion of the whole, where in your judgment it would be impossible to take away the sense of pain?—Yes.

3037. If an experiment has once been performed, and the result completely established, do you hold it to be necessary to have a recurrence to that experiment?—Well, that opens the question when is a result completely established? That is a question which is not perhaps at all times very easy to answer. There must be a certain verification of experiments. Men of science do not as a general rule admit a new proposition without testing it.

3038. Supposing a proposition to have been so tested as to have been generally admitted, and the process of arriving at it to have been very painful, would it in your judgment be justifiable to have recurrence to it?—With regard to such experiments for example as I have referred to in connexion with the brief history of the subject that I have given, they of course are admitted, and I do not see that there would be any necessity to repeat them for the mere purpose of instruction.

3039. Experiments of this kind ought to be performed, I presume, by very competent persons?—Certainly.

3040. It would be unjustifiable to perform an experiment of this kind in the case of a person who is untrained, or inexperienced, or ignorant?—Certainly.

3041. Is the number of persons who, in your judgment, could usefully perform experiments of this kind very great?—Not in this country.

3042. Would the restraint of such persons, that is to say, incompetent persons, receive your approval?—Then would arise the question who is to judge of the competency or incompetency of the person.

3043. No doubt; but I suppose that, for instance, in Edinburgh, it is pretty well known to yourself and to those eminent men with whom you act, who are competent and who are not?—Undoubtedly we know who are competent; but I am not prepared to say that I know every one who is competent. There may be persons competent, and of their competency I may not be aware.

3044. Everything human is more or less exposed to uncertainty perhaps, and difficulty; but is it not as certain who are competent people to perform painful experiments as who are competent in almost any other branch of knowledge or practice?—Undoubtedly with regard to men who are well known, who hold official positions, positions as teachers, and so on, of their competency we may be well aware. We may assume that. But still there may be persons who are quite competent to perform experiments, and who might advance not only physiological science but also the healing art, with whom I and others are not acquainted.

3045. Must not a person to become competent pass through some school and receive some teaching?—Certainly.

3046. And will it not be known to those who have taught him whether he is a competent person or not?—I suppose that one may to a large extent admit the accuracy of your view. I do not wish to refine too much in the matter, but still I do not wish to commit myself to the statement that I know, in Edinburgh for example, all competent persons. That is the only exception I wish to be made.

3047. Making that exception, you would argue that speaking generally it is pretty well known, or may be known, who are the competent persons in a country to pursue such investigations as those of Harvey, or Jenner, or Jones?—Yes, speaking generally.

3048. Now would it be in your opinion any restraint upon physiological science if the performance of painful experiments upon living animals were limited to those who are known to be competent?—If you mean limited by legislative measures I have difficulties in the way of legislation on this matter. Perhaps you would allow me to state them. In the first place I have a difficulty in connexion with the expression which I find in the letter of your secretary to me as to the object of the Commission, "the practice of subjecting live animals to experiments for "scientific purposes." In what sense are you to employ the term "live animal" or "living animal." Is it to be supposed that the meaning of the term "living animal" is to be defined by Act of Parliament? I apprehend that if there were to be legislation on this matter it would be necessary to lay down what is a "living animal" or what is "life." Now to give a definition of life has been a difficulty from the time of Aristotle to the present day; and by referring to the history of physiology you will find that physiological writers are by no means agreed as to what is meant by the term "life." Take a frog, for instance, that has had its head cut off, the muscles and nerves of which are capable of responding to a stimulus; are we to consider that frog a living animal? There is a difficulty. A frog in that condition, with its head cut off, and with its muscles and nerves capable of responding to a stimulus, is an animal of the utmost importance in physiological research. There is life in the muscles and life in the nerves so far as regards the capability of responding to a stimulus, but that is not life in the animal itself according to the ordinary conception of the term; so that this is a difficulty which faces me at the very onset—are you to define by Act of Parliament and determine by statute what is a living animal?

3049. Then one of your fundamental objections, or perhaps the fundamental objection to any interference by the legislature is the difficulty of drawing a distinction between an animal that is living and an animal that is not?—Yes, that is a difficulty.

3050. Are there any other difficulties?—Then I find a difficulty in this respect, that vivisection is by no means exclusively practised by men of science; that vivisection is extensively performed by others than men of science; and that if restrictions are to be made by legislative enactments for the purpose of preventing men of science from operating on living animals, one does not see why in common justice others should not be also prevented from cutting living animals, and yet, if this were done, it would lead to difficulties and complications in one of our most important industrial occupations. I may just give by way of illustration of this matter some few facts that I have collected with reference to the practice of vivisection on the farm. I was inquiring the other day of a farmer on the Borders, who has a large number of sheep, how many lambs he had in the year. He told me he had 600 lambs, that was his average number. I said "How "many of these lambs are males?" "About half the "number." "Do you castrate these males?" "Oh yes; "we castrate them; we castrate some 300 lambs each "year; and in addition to castrating them, we cut off "their tails, or we remove considerable portions of their

Mr. W. Turner, M.B.

26 Oct. 1875.

" tails; we find it useful to have the animal's tail " shortened. And then in addition it is necessary ' also that the lambs should be marked, which is done " partly by snipping portions out of the ears, and " partly by branding them." Over the whole country therefore many thousands of lambs are annually subjected to the painful operations of castration, tail docking, and branding, without chloroform or other anæsthetic being administered either by the farmer or shepherd. Moreover, calves and colts are also castrated in large numbers annually. Now all these are vivisections practised upon living animals for certain purposes—important purposes undoubtedly, because they improve the quality of our mutton and beef and make it more palatable to the consumer, or enable the farmer to recognise his own flock from that of his neighbour, or furnish us with more useful beasts of burden than if entire horses were employed.

3051. But suppose the object of the legislation was to confine scientific experiments to persons of the highest competence in science, and to exclude from the performance of such experiments those who had not got that competence, would that hinder the progress of scientific discovery?—Well, I can see difficulties even in that matter. I can imagine that cases of importance might arise in which a man who has not an established name in science might find it necessary to perform an experiment on a living animal; and if you will allow me I will give you an illustration. Suppose that a medical man in some country town or district is attending a patient with certain symptoms, which perhaps he may consider to be due to the administration in the food or medicine of a poison by some one in the house of the patient. We know that a very good means of determining the poisonous action of a substance is by administering a portion of that substance to a living animal, and by watching its effects on that animal. In such a case as I refer to, the medical man in charge might obtain a portion of the suspected food or medicine administered to the patient, and give that to a living animal, and so from the symptoms observed on that animal ascertain whether it contained poison. Now if you were to restrict the experimenting on living animals only to such competent persons who let us say had been licensed to employ animals for scientific purposes, you would prevent this medical man, unless he happened to be one who had been so licensed, from administering the suspected matter to an animal, and so perhaps the life of his patient might be sacrificed.

3052. Would not it be more natural in that case for the medical man to analyse the medicine or the food?—That is undoubtedly one method of getting at the result; but a large number of medical men have not the necessary knowledge to perform a careful analysis, and there are many substances that when mixed with food, or with various medicaments, are extremely difficult indeed to detect; and a much more simple way of detecting their presence would be by an experiment on an animal. Take, for example, strychnia; strychnia is a substance extremely difficult to detect by analysis, except by an expert, but the administration of something containing a solution of strychnia to a living animal very soon shows its presence by the tetanic symptoms produced.

3053. Would you have the patient go on taking the suspected medicine or food while the animal was being experimented on?—The experiment could be performed without any loss of time, so that the poison, if present, could be at once detected, and there would not be the delay which would be required if a complex chemical analysis had to be performed.

3054. Another principal objection of yours to legislative interference would be the prevention of a medical practitioner who by the hypothesis is not competent to analyse food and medicine, from trying experiments on living animals as to the effects of that food or medicine?—That is one of my difficulties.

3055. Are there any others?—There is another difficulty, that when legislative checks are enacted, the progress of discovery in science is likely to be impeded. I might put this case: suppose that Galvani had lived in a country where legislative restrictions had been in force, and that he had not been a person who had received a license to practice on living animals, he might have been stopped at the outset of his discovery, and the whole progress of electrical science might have been delayed for half a century or more. I think this, that it would be unwise by legislative measures to do anything that would be likely to check the progress of science, because I hold that the welfare of mankind is intimately bound up with scientific advancement.

3056. But supposing that it be admitted for the sake of the present argument that nothing is to be done which will check the advancement of science, would it not depend upon the nature of any restrictions which the legislature might impose, whether they would have that tendency or not?—If there is nothing in the legislation to check the advancement of science then of course this part of my argument disappears. What I feel is this, that as a man pursuing a scientific career, I have a difficulty in admitting the wisdom or expediency of making any legislative enactment that would be likely to interfere with the progress of science.

3057. (*Lord Winmarleigh.*) I understand that those three points that you have given to us, you have brought before us as instances of benefit derived from vivisection which would not have been derived from any other source than from experiments on living animals?—I have.

3058. Do you think that there is an impossibility of a similar benefit being derived from experiments on human bodies?—If you could get human bodies to experiment on.

3059. I mean you do not see any reasonable means of getting at those facts through human bodies?—I do not.

3060. Do you think it would be possible to place before the Commission an accurate list of all similar benefits which have been derived from vivisection, from the earliest times to the present?—It would be a work of labour.

3061. Do you think it is possible to do it?—I think it is possible to do it, but it would be a work of considerable labour, more especially in reviewing the progress of science in late years.

3062. But you seem to have paid attention to that particular point; could you, not now, but hereafter lay before us some of the main discoveries that have been made by vivisection, and which could not have been made without experiments on animals?—I could do so if you gave me time to get the facts together, but it will take time.

3063. But indisputable facts?—I hold that these facts which I have laid before the Commission to-day are indisputable facts.

3064. You think that you could with time furnish the Commission with a list of similar experiments which could not have been made by any other means than through experiments on living animals?—I think so.

3065. (*Mr. Forster.*) With regard to these three cases of which you have given us an interesting account, take first the discovery of the circulation of the blood; at that time there were no anæsthetics; do you imagine that those experiments, if the discovery were now to be made, could or could not be conducted under anæsthetics?—I think that Harvey's experiments might have been conducted under anæsthetics.

3066. And now take the lacteal and lymphatic vessels, in that case could they?—Most certainly.

3067. The nervous experiments could not, I suppose?—In part, but not altogether.

3068. Then with reference to two out of the three altogether, and in regard to the last in part, anæsthetics could have been used?—Yes.

3069. (*Sir J. B. Karslake.*) How many years have you been engaged as lecturer on anatomy in Edinburgh?—I have been engaged for 21 years.

Mr. W. Turner, M.B.

26 Oct. 1875.

3070. Have you a considerable number of pupils under your charge?—The largest class in Great Britain.

3071. About what would be the average of that class?—My numbers last winter were 468.

3072. Now, are many of those students also attending lectures on physiology?—About from one-third to one-half of those students.

3073. And they therefore have the advantage, if it be an advantage, of witnessing the demonstrations by the gentleman who was last before us, Professor Rutherford?—They have.

3074. Do you know many of these gentlemen privately, so as to know what their work is?—Some small proportion, but out of so large a number of students drawn from all parts of the world, only a small proportion have I any very intimate acquaintance with.

3075. From anything that you have heard about them, are you induced to believe that they practise vivisection in private?—I have no knowledge that they do.

3076. Have you any reason to think that they do?—It is possible that a student may occasionally, but certainly there is no practice of it, that I am quite clear about. I am not prepared to say that here and there a student may not do it, but certainly it is not the practice. On that I can speak, I think, without hesitation.

3077. Now passing from students, do you think that after they become medical practitioners themselves, they carry on the practice of vivisection to any extent?—Certainly not.

3078. Have they either the time, generally speaking, or the opportunity of doing it?—They have neither the time nor the opportunity, nor, I think I may say, the inclination either.

3079. As far as you have observed, is the tendency rather against vivisection on the part of those gentlemen than in favour of it?—I think that on the part of most men in this country there is a repugnance to experiment on a living animal. I have adduced evidence from the writings of Sir Charles Bell, and the writings of Dr. Jones, that both those gentlemen experimented on living animals unwillingly; and with regard to myself, when I have to do it for my own private researches, it is only resorted to when there is a feeling of its being of paramount importance.

3080. And as far as you have had any opportunity of observing, is that practice which you say you follow yourself followed by others?—Such is my belief.

3081. (*Mr. Huxley.*) I should like, following up the question that Lord Winmarleigh put to you just now, to inquire whether, in addition to the cases that you have put before us a great number of similar cases might not be produced?—They might undoubtedly.

3082. Suppose I take the several functions. Take digestion, for example, is it possible that our knowledge of that function could be what it is, without the knowledge which we derive from vivisection, and vivisection only?—Certainly not.

3083. Take secretion, and reminding you of the late experiments on the action of the nerves on the glands, let me ask you, could we have any conception of what that consists in without vivisection?—No conception.

3084. Turn to the important functions relating not only to the circulation but to the distribution of the blood over the body, one of the most important of all matters in regard both to healthy and diseased states, would it be possible for us to have any notion about them without vivisection?—The action of the vaso-motor nerves, which are the regulating nerves of the blood vessels, can only be got at by experiment.

3085. Then I will take a matter of importance alike to pathologists and physiologists, the whole doctrine of the inhibitory nerves, or those nerves the function of which is to arrest the action of the other parts?—That knowledge can only be got at by experiments.

3086. Indeed, I may say, may I not, with respect to the functions of the nervous system generally, that we should be absolutely in the dark respecting them, except for experiments on living animals?—Yes; anatomy had done all that it could do; experiment was absolutely essential to work out the function of the nervous system.

3087. To pass from the nervous system to organs such as the kidneys, what possible mode could there be of ascertaining whether the formation of urea takes place in the system generally, or in the kidneys, except by experiment?—I do not know of any.

3088. To take next the whole reproductive functions, may I ask you whether, from the first, our knowledge of the essential nature of that process in the higher animals is not entirely due to experiments such as those of Bischoff?—And the experiments of Harvey.

3089. It has been suggested before us frequently that this method of experimentation which is now practised is something newly introduced into physiological science, but I think that the cases which you have quoted have sufficiently refuted that statement?—I think so.

3090. Then as regards the undoubted fact that such experiments are more largely performed now than they were 30 years ago, is it not the case that that has arisen, not from the introduction of any new method, but simply from the greater thoroughness of teaching in physiology now as compared with the teaching of physiology 30 years ago?—Partly from the introduction of a greater thoroughness of teaching, and partly, I think I may also say, from a great scientific revival. The tendency of the present day is undoubtedly towards scientific advancement and progress, more men have given their minds to science, and consequently there are more workers in the field.

3091. Then as respects the use of experimental demonstration for teaching, it is very hard for those who have not been occupied in scientific research, to understand the great difference which there is between a person who is acquainted with a fact at first hand and a person who knows it only by hearsay; but it will be within your knowledge that in every branch of physical science it has been considered within the last 30 or 40 years to be of fundamental importance to give the student practical instruction?—That is a matter about which there can be no dubiety at all. The whole tendency of modern scientific teaching is to make the education practical.

3092. I suppose that if there is any one thing of which it might be hoped or expected *à priori* that you could teach it just as well by books and pictures as you can by practical work, it would be anatomy?—Yes, but I should attach no value to anatomical teaching that was not practical.

3093. That, however, is a clear case of mere structure?—Yes.

3094. And you can give exceedingly good pictures of a leg or an arm, and probably you can convey a better image of a thing without seeing it in anatomy than you can in anything else?—Yes, I think so.

3095. And yet I suppose you, as a professor of anatomy, would simply laugh to scorn the idea of making a man an anatomist without dissecting these parts practically?—Most certainly so.

3096. And it is the case with every branch of science, is it not?—I believe so.

3097. Your University of Edinburgh is at present making great sacrifices, and has been collecting large sums of money for the purpose of very largely extending its practical teaching?—Yes.

3098. So that, taken together with the development of laboratories in all parts of the Continent, shows that there is a complete and general consensus amongst those who are practically acquainted with this matter, that practical teaching is absolutely necessary?—It does.

3099. You, I think, are one of the editors of the Journal of Anatomy and Physiology?—Yes, I have been so from the commencement.

3100. So that you are, as a matter of business, obliged to keep up a knowledge of what is doing in

Mr. W. Turner, M.B.

26 Oct. 1875.

Great Britain and elsewhere ?—Yes, it comes before me naturally.

3101. And I suppose you can tell us whether those countries in which practical research is the most systematic and the most thorough are not those which furnish you with the largest quantity of new discoveries ?—The greatest amount of new material comes from Germany, which is the country where practical instruction and training in scientific methods are probably most systematically and actively carried on at the present time.

3102. I think I understood you to say that you had a general objection, as a matter of principle, to legislation on the question which is before us, because you considered that it would be making a law for a particular class of so-called offences when precisely similar offences, it they be such, would be committed on a vastly larger scale, and would not in any way be affected ?—That is one of my difficulties; I think it would be class legislation of a most offensive and objectionable kind.

3103. If I am not greatly mistaken, that is a feeling which is shared very strongly by sundry of your colleagues and other persons of eminence in Edinburgh ?—I think so.

3104. Now it has been suggested that it is possible to control practices in physiological laboratories by some system of inspection, has it occurred to you to consider how that would work in practice; and I ask you, as knowing so thoroughly the real manner in which these things do work ?—I am familiar, and have been familiar ever since I became a teacher of anatomy in 1854, with the workings of an Act applicable to anatomists called the Anatomy Act. All anatomical teachers are subject to inspection—a government officer, an inspector of anatomy, is appointed by the Home Secretary, and all anatomical schools are inspected by this official under the Act of Parliament in question. But there is a difficulty, perhaps, in applying the same principle to physiological teaching, in this way, before the Anatomy Act the practice of anatomy was illegal, there were no legal means of obtaining bodies for dissection before the passing of that Act, excepting the bodies of those who were hanged; and the Anatomy Act, although called an Act for regulating the schools of anatomy, really in its operation is an Act for facilitating the practice and pursuit of anatomy, because the Anatomy Act provides us by legal means with the material which we have to examine in our anatomical work. If a system of inspection could be introduced which would not hinder the progress of physiological inquiry, or prevent a practitioner from acquiring knowledge for the benefit of his patient, I should see no difficulties in it, but if a measure of inspection were to be introduced which would hinder the progress of physiological inquiry and medical research, then on the grounds that I have stated in the earlier part of my evidence, I should have an objection to it.

3105. The duties of the inspector of anatomy are exceedingly simple, I think. I think that his business is simply to see that the bodies which are dissected in your theatre, for example, have been legitimately come by ?—That they have been legitimately come by.

3106. And when he has satisfied himself about that point, and that they are properly buried, he has nothing else to do ?—Nothing else.

3107. But supposing that it was part of the duty of the inspector of anatomy not only to see to these points, but also to see that you did your dissection properly, and that you did not employ clumsy people in making dissections, and to satisfy himself that you were not employing people in making useless dissections, do you think it would be possible that your teaching could go on ?—It would be quite impossible, because it would be making the inspector of anatomy, who probably would be a person without any special anatomical knowledge, a judge over experts.

3108. In the case of an inspector of physiological laboratories you have two alternatives, either he must be a person who knows something about it, a competent judge, or he must be a person who does not know anything about it, or knows very little about it. If he is a competent judge it has been suggested that he would in all probability be in sympathy with the scientific person who was in the laboratory, and that his inspection therefore would be of no good. If he is an incompetent person, on the other hand, however well educated a person he might be, I presume that the difficulties you have just referred to would infallibly arise, that is to say, he would be unable to comprehend the drift of your experiments, and he might very often report that you were doing barbarous and horrible things when you were doing that which was perfectly right and necessary. I am not putting that difficulty to you merely speculatively, but I am basing it upon what has actually occurred. I presume that you could not meet with a more respectable and in many ways excellent body of persons than the committee who manage the Society for the Prevention of Cruelty to Animals. I have every respect for them and their efforts. But a representation from that committee has come before us, containing statements respecting cruelty said to be perpetrated on animals. One of those statements upon which a formal assertion of cruelty, although it was excused, has been put forward was this, namely, that a lady teacher had taken a lobster to a class, and had cut it up before her pupils, the lobster being alive and moving about after it was cut. The whole evidence, as a matter of fact, was that the lobster in being cut moved its limbs. Is that evidence in your opinion that the lobster was sentient, or may it have made those movements as a purely reflex action ?—There is no evidence from a general statement of that kind that the lobster was a sentient creature, and in my opinion it was not, because we know well that movements will occur from reflex action where there is no consciousness either of the movement or of the application of the irritant which may have occasioned the movement.

3109. In other words, if the persons who reported upon that case had had any instruction in elementary physiology, they would not have dreamt for a moment of basing a charge of cruelty upon that fact ?—Most certainly they would not.

3110. Then I apprehend that, as a physiologist, you would not feel very happy if your laboratory were inspected even by persons of that degree of respectability and good faith, and it were left to them to report upon what they might think was wrong ?—I think it would be most dangerous.

3111. In fact, physiologists under these circumstances would probably be incessantly worried by charges which had no sort of real foundation ?—I think I would go so far as to say this (it may be, perhaps, a somewhat strong statement to make), that if physiological laboratories in this country were put under the inspection and supervision of persons of that kind we should become the laughing stock of scientific Europe; that is my strong conviction.

3112. (*Mr. Erichsen.*) To pursue the subject that Mr. Huxley has been inquiring into, in the event of a method of inspection being devised that would not be oppressive to physiologists, or that would not be a check to physiological science, do you think that there would be any objection to that? No such method has as yet, I believe, been devised or proposed ?—I should like to have an opportunity of seeing the proposed method before I answered the question.

3113. I think one of your objections to legislation was this, you stated that there was a difficulty in the definition of the words "living animal," and you illustrated that by the case of a frog whose head had been removed, and who still possessed the capability of automatic movements ?—Yes.

3114. But in that case is not the commencement of the experiment the removal of the brain or head, and up to that time the animal is certainly a living animal, and the experiment commences when the brain or head is removed, and everything subsequent is upon an animal in that condition ?—Undoubtedly, Mr. W. Turner, M.B.

26 Oct. 1875.

if the removal of the head of the frog were to be regarded as an essential preliminary to the performance of the experiment, the removal of the head would be the beginning of the experiment, but most persons would regard a frog as killed when its head was cut off, and that any experiment afterwards performed was on a dead, and not on a living animal.

3115. I think that with regard to this matter of inspection, or of licensing, or at all events of legislative interference in some way or other, there is one view that may be taken, and it is this, that as matters are at the present moment I suppose that any man can, if he has the time and the means, engage a room and pursue any kind of physiological inquiry that he pleases, provided that he keeps himself free from the operation of the Act for the prevention of cruelty to animals?—So far as I know it is so.

3116. And that any man might pursue a chimera. A man might, for instance, wish to ascertain the seat of the soul or the seat of life, (and I will give you in an instant an example of a very eminent man who wished to do so,) and he might immolate many thousands of animals in the pursuit of that chimera in trying to find the seat of the soul or the seat of life, and there is nothing to interfere with his doing so? Is not this the case at the present time. If I, for instance, as a medical man, chose to investigate the seat of the soul, or the seat of life, or had ideas about that, I might experiment on any number, on hundreds or thousands of animals that I chose to immolate in pursuit of that chimera?—Well, I am not sufficiently conversant with the exact working of the Act to answer that question.

3117. There was a very eminent man who is now dead, Dr. Stevens, who was a great surgeon; he first tied the internal Iliac artery, and he performed a great many physiological experiments upon the blood, and some experiments on Asiatic cholera. I was very well acquainted with him, and in the later years of his life he was seized with a great desire to ascertain the seat of life. I do not know that he experimented, but he wrote a great deal and talked a great deal about it, and he might have experimented to any extent. He had been an experimenter and a successful surgeon in early life, and might have gone on experimenting to any extent in pursuit of what most of his friends thought were mere idle fancies. So that, I think, there is that view with regard to the possible expediency of some kind of inspection?—Then who is to be the judge?

3118. That I know nothing of. Then I would take another point which you stated in reference to this very matter, namely, that a practitioner in the country who had a case of suspected poisoning might find it necessary to experiment on animals in order to ascertain what poison his patient was probably suffering from. We know that there have been cases of that kind which have now and then occurred. But is not that case analogous to the case of a country practitioner having to perform a surgical operation which he has never done, and who wishes to refresh his knowledge of the anatomy of the parts concerned in that operation; he is precluded by the Anatomy Act from taking a dead body into his house in order to do it, and he comes (as I know to my certain knowledge men have done) to a London school, or a central school, and there dissects the part on which he is afterwards going to operate. Will it not be possible for the medical practitioner in the majority of cases, at least in the cases of suspected poisoning, and making the necessary experiment in some central school that is legalized or licensed, to obtain in that way the information that he wished to acquire?—That is just a point that I have considered, and I think I can show that the cases are not strictly comparable. There are certain operations which have to be performed by the surgeon, and which must be done without delay, relying upon the knowledge which he possesses—he has no time to resort to schools of medicine, dissecting schools, and so on—I refer to such operations as the performance of tracheotomy in impending suffocation, and the performance of the operation for relief of strangulated hernia. I would cite those as comparable with the case I put just now, not such cases as excision of joints, where the operation may be put off for a time, and where the practitioner may revive his anatomical knowledge by going to a medical school to make a special dissection.

3119. But I am speaking of a case of chronic poisoning, because it is the cases in which you have suspected chronic poisoning that you make the experiments on animals?—This feeling, however, I think must act on the mind of any practitioner who is in attendance on a case of such a kind, that the sooner it is settled the better; that if there is some one in a house administering poison to a resident in that house the sooner the administration of that poison is checked the better. It should be done at once; and it is just in the case of a vegetable poison, such as strychnia, the detection of which in organic fluids by ordinary chemical analysis is so very difficult, that a rapid solution of the question is desirable.

3120. But still, as there would be many central schools licensed all over the country, in all of the large medical schools and most of the great towns, no medical practitioner would be many hours removed from one of those centres; and it seems to me that, practically, the difficulty would not be very great?—Undoubtedly what you have stated does to some extent remove the objection which I have raised, but I am not prepared to say that it altogether removes it.

3121. In addition to those cases which Professor Huxley brought forward, in which there was direct advantage obtained by physiological investigation, direct advantage to science, and indirectly, perhaps, an advantage to the treatment of disease, and so on, I would ask you, as it might be interesting to some members of the Commission, about two or three other cases that have a direct bearing upon the treatment of disease, whether surgical or medical. One, for instance, is the whole subject of asphyxia; the nature of that process, the gases that are respirable and irrespirable, and the influence of artificial respiration has been worked out, has it not, during the last century or more by a series of experiments on animals?—Yes, it has.

3122. And could not have been ascertained otherwise. For instance, is it not the case that it was generally believed that a person who was drowned was drowned by swallowing water, or by the water getting into his lungs and filling them up, until it was proved by experiment that such was not the case?—I believe that was the idea.

3123. And it would be impossible to subject human beings to the experiment of breathing irrespirable gases?—Yes.

3124. Those experiments must be made necessarily on the lower animals?—Yes.

3125. Then, again, if we take a subject which is of considerable importance in surgery, namely, the reproduction of the bone from the periosteum, the method of union of broken bones, and of bones that have been partially excised, and the method of the repair of tendons, all that has been, or at least a very great part of it has been, worked out by a series of experiments upon lower animals by physiologists and surgeons in France and a number of surgeons in this country?—Yes, certainly.

3126. Then, again, if we were to take that disease called diabetes, it was supposed, not many years ago, that the sugar was formed in the kidneys; it is now known by physiological experiment that the sugar may be produced by a lesion of the nervous system. Claude Bernard has shown, that if a certain portion of the brain is injured you get sugar in the urine; that the sugar has nothing more to do with the kidney, and is no more a kidney disease, in point of fact, than the purulent expectoration in a consumptive patient has to do with the mouth; that the kidney merely evolves it from the system just as the mouth ejects the purulent matter from the lungs?—That is the case.

3127. (*Mr. Hutton.*) You seem very much afraid of preventing any competent person from making these inquiries; but I thought you did not seem very much afraid of allowing incompetent persons to make them?—I think you can hardly have taken my answer correctly. I think I raised the objection who is to judge whether a person is competent or incompetent; there is my difficulty.

3128. That is precisely my point. Supposing that any system of restriction practically did prevent a few competent persons, but also a great many incompetent persons, from making these experiments, is not the loss on the one hand much more than balanced by the gain on the other?—That is a question which I am not prepared altogether to answer in the form in which you put it, because I hold that competent persons ought not to be restricted, and I should be sorry to see any measure introduced which would prevent competent persons from conducting experiments which they may conceive to be of physiological importance and of practical value.

3129. That comes, does it not, to what I said, that you are much more afraid of preventing competent persons than of not preventing incompetent persons?—I am not prepared to say that in this country experiments on living animals are carried on by incompetent persons.

3130. Now you spoke with very great confidence as to the fact that medical students in Edinburgh do not perform these experiments in their own private rooms?—I have no reason to believe that they do.

3131. We have had before us the statement of a gentleman signed by him, who probably was one of your own pupils, Mr. James B. Mills, M.R.C.S., who states that in his first session he saw a few of these experiments, and that in the following term, having become a senior, he was introduced to a great number of such vivisections, and on some occasions operated himself?—I have no knowledge of Mr. Mills at all.

3132. But do you not think that in all probability, if these things did happen at all, they would not come to your knowledge rather than that they would?—I think that if there were any abuse at all it would come to my knowledge.

3133. At all events, if this statement is true, here are a number of experiments which have happened of the kind which you would object to, and which did not come to your knowledge?—I am not prepared to admit anything about the statement, because I know nothing of the individual making it.

3134. I hope we shall have him before us, and shall know from him how far the statements can be confirmed. Then, again, you take a strong objection to putting any kind of restrictions on these experiments, on the ground that no such restrictions are put in the case of farmers and shepherds who perform these kinds of experiments on living animals. Is there not this great distinction between the two cases, that in their case it is obviously to the interest of the persons who perform those experiments not to do more than the necessary injury to the animal in question, while in the other case the interest is purely scientific, and the welfare of the animal itself is in no respect the interest of the operator?—I am afraid that you do not in that question altogether recognise the conditions under which a scientific experiment should be made; because it is most certainly to the interest of the experimenter that the animal should be injured as little as possible, just as much as it is to the farmer's interest that the animal should be injured as little as possible. One of the great conditions of experimenting on animals is that you should inflict as small an amount of pain and disturbance as possible; the greater the pain or the disturbance that you occasion to the functions of the animal the less your experiment is likely to answer; you must minimise the pain and minimise the disturbance.

3135. Surely such an answer as that has no application at all to such an experiment as poisoning an animal by strychnine for the purpose of demonstration to a class?—I do not think that I cited that experiment at all in connexion with class demonstration.

3136. There must be surely numberless experiments in which the experiment made is perfectly made whether the animal is more or less injured by the experiment. Of course, if it is an object to save the life of the animal, or if it is an object to prevent any disturbance to its system, except for the particular object of the experiment, what you say is perfectly true; but there may be plenty of experiments, may there not, in which that is not the object at all?—Many experiments undoubtedly result in the death of the creature; there is no question that many experiments must result in the death of the creature.

3137. And in those experiments there very often can be no identification, except such as humanity causes between the welfare of the animal and the object of the operator?—I must again repeat (because I think this is a matter of cardinal importance in connexion with this inquiry) that it is of the utmost importance in physiological experimentation that as little pain and as little disturbance of the function as possible should be occasioned to the creature, and that it should all be done as gently and as humanely as is possible, because, unless it is so done, so many disturbing elements are brought into the case that it is excessively difficult to interpret the experiment.

3138. On the other hand, it is often essential that there should be pain. For instance, your colleague, who has just preceded you, has shown that a variety of experiments could not have been tried without giving pain to the animal, and that he was not able to give anæsthetics on that ground?—Undoubtedly in those experiments which have for their object the sensibility of the nerves, pain must be given; but anyone with ordinary humane feelings would minimise that as much as possible.

3139. That is always assuming, as you seem to assume throughout, that the operator will be a man of these highly cultivated feelings and of the proper competence?—But I have no reason to think that men who practice experiments on living animals in this country are not humane men.

3140. But supposing that that could be shown, and a case of that kind could be made out, in that case you would give up your argument?—I do not know that I am called upon to consider a hypothetical case of that kind. I have no experience of that sort; my experience is the other way.

3141. Is it not true that the greater number of practitioners now living have learnt physiology without any practical teaching of the kind that is involved in painful experiments on living animals, and most of them without any experiments on living animals at all beyond those of course of the hospital and their ordinary private practice?—There is no doubt that physiological teaching up to within a comparatively recent period was not practical teaching; there is no doubt that it was merely teaching from lectures and books.

3142. Would you not say that a large number of the practising physicians and surgeons now living have had very little of this particular kind of teaching?—I think, as far as my knowledge goes, that there was very little practical teaching of physiology in the schools of medicine in this country until within a recent period. It is only indeed within a recent period that it has become strongly impressed upon the profession, and the various authorities in the profession, that practical teaching in physiology is required and is necessary. That is a matter which the medical authorities have only of late years satisfied themselves of and regulated for.

3143. But strong as your impression is that it is requisite, you would shrink from saying that all the eminent men who never have had that teaching are incompetent on that account?—But I think you will find, if you go into the histories of these eminent men, that although they may not have had teaching in practical physiology in the schools they taught it to themselves. If you look at the life of the late Sir Benjamin Brodie, or if you go back to the earlier years of Sir James Paget, and men of similar eminence in the profession, you will find that they were all practical experimenters in their younger years. In short, that has been undoubtedly one of the means by which men have risen to eminence in the medical profession.

3144. One, but not the only means ?—I say one of the means and a most important means. They have employed the earlier years of their life in experimental physiological inquiry, and on the knowledge acquired in their earlier years they have based their practice.

3145. But you would shrink from saying that no eminent men are now practising who have not obtained their knowledge in that way ? — It would require a more extensive acquaintance with the earlier life of men now in practice than I possess before I could say that; but I could mention many. I have told you of the late Sir Benjamin Brodie and Sir James Paget, and I will add Sir George Burrows; all to my knowledge men who have practised experiments and published their researches. But it should be remembered that those who may not themselves have practised physiological experiments have yet availed themselves in their methods of practice of the conclusions arrived at through the experiments of others. Perhaps you would allow me, in supplement to what I have just stated, to say that there is no question at all that many physiological experiments can be done without injury to living animals. A large number of experiments, for example, on chemical physiology, do not require living animals to be killed or injured.

3146. As to your impression that there would be a certain degradation to the profession in any kind of restriction being imposed, surely you would not say that there was any degradation to the millowners in the restriction that was put on the employment of children as factory hands in the mills ?—I do not think I used the word " degradation ;" I have no recollection of employing that expression.

3147. I think you employed some sort of equivalent for it ?—I have no recollection of using such an expression.

3148. In that case, then, did I misunderstand you as saying that the profession would feel injured as a whole by any restrictions ?—The expression I used was, that if such persons as were referred to in the question put to me (3111) were made inspectors of physiological laboratories we should become the laughing stock of scientific Europe.

3149. It was to a different part of your evidence I was referring. I understood you to say that the profession as a whole would feel injured by the assumption that any inspection was necessary ?—I have no recollection of saying anything of that sort. I do not think that I should be prepared to give any opinion as to what the view of the profession on the matter would be. I am merely giving my own opinion.

3150. And it is not your own opinion, then, that there would be any kind of slur cast upon medical men by that kind of inspection ?—I am not prepared to say that there would be a slur cast upon medical men by it. My argument was that I feared the progress of scientific discovery would be impeded.

3151. (*Chairman.*) I think I understood you to say that before giving any opinion about restrictions you would like to know definitely what those restrictions were ?—Yes.

3152. I think you said that there would be a difficulty on your part if there were any hindrances to the progress of scientific inquiry ?—That is my great difficulty.

3153. I think you said that you particularly wished to impress upon us that it was the interest of the scientific inquirer to avoid any disturbance of the animal subject to experiment, because it interfered with the success of his experiment ?—I said so.

3154. From that I daresay we may infer that, in your opinion, an experiment, to be useful to science, must be performed by the most competent persons ?—Certainly.

3155. And that if such experiments were performed by bunglers and incompetent people, not only would they be objectionable on the ground of inhumanity, but they would be comparatively misleading, and not tending to promote the progress of science ?—Certainly.

3156. Then with regard to the argument from the form I understood you to say that many of the scientific experiments were not more painful than other things that are done in other modes of life ?—Yes.

3157. But I do not understand you to found upon that any argument for an absence of humanity in the prosecution of scientific inquiry ?—Most certainly not.

3158. Nor if it be admitted to be necessary that certain things should be done upon a farm, do you found upon that any argument why bunglers should perform scientific experiments, or why eminent and most scientific men should perform unnecessarily, or with indifference to humanity, those that they do feel obliged to perform ?—Certainly not.

3159. Then with regard to the inspector of anatomy, I understand you to say that you feel no sense of class legislation in regard to that appointment, but that if a person not of the highest eminence in physiology were set to inspect and report upon the most eminent men in physiology you would think that to be injurious to those eminent men, and also injurious to the progress of science ?—I do not know whether I have sufficiently brought out what I intended, that there is to me at least a difference between the Anatomy Act and an arrangement as regards physiology such as seems to be indicated from what has transpired. The inspector of anatomy has nothing whatsoever to do with the methods or object of the dissections conducted in the localities which are licensed for the purpose; all that he has to do is to be satisfied that no subjects are received in the apartments licensed for purposes of dissection unless they have come through a regular official channel, and that when the anatomist has pursued his dissection to completion, the bodies are removed for decent interment. Those are all the duties that the inspector has to perform. An Act for the physiologist parallel to the Anatomy Act would provide and regulate a supply of frogs, rabbits, and other living animals to the schools of physiology, and see to their removal from the schools after being used, but would not take into account any experiment performed upon them when in the schools.

The witness withdrew.

Mr. J. C. Browne, M.D.

Mr. James Crichton Browne, M.D., called in and examined.

3160. (*Chairman.*) You are the head of the lunatic asylum at Wakefield ?—Yes; the West Riding Lunatic Asylum.

3161. Has your attention been directed particularly to the subject into which we are appointed to inquire ?—It has for ten years past.

3162. Do you yourself practice experiments on living animals ?—I have practised experiments, not what I should call vivisection, that is to say, I have never cut a living animal with the knife, nor operated upon one in any way, but I have experimented with drugs on living animals.

3163. What has been the nature of your experiments ?—My own experiments have consisted of two series, one undertaken last year, in which there was no destruction of life, to ascertain the actions of nitrite of amyl, and another undertaken last spring, with a view of testing the antagonism existing between certain drugs. There is a poisonous substance called pycrotoxine, the essential constituent of coçculus indicus, and I instituted a series of experiments to ascertain whether chloral was antagonistic to that substance, and I succeeded in proving that after a poisonous dose of pycrotoxine has been given to an animal if a dose of chloral be given subsequently the animal will recover.

3164. Have you tried that upon many animals?—In my whole series of experiments 46 were sacrificed.

3165. What kind of animals were they?—Rabbits and guinea pigs, one dog, and a few cats; chiefly rabbits and guinea pigs.

3166. Did it operate upon them all?—Upon them all.

3167. I suppose the occasion has never yet occurred of a human being being poisoned by this poison of which you speak?—Yes; there are several cases on record.

3168. But since that period there has been no case of a human being to your knowledge being poisoned by it, upon whom the supposed remedy has been tried?—No; cases of poisoning by pycrotoxine are of very rare occurrence.

3169. Now have any other persons practised experiments upon living animals in your laboratory?—Dr. Ferrier's first series of experiments was carried out there nearly three years ago.

3170. Were you present?—I was present at all of them.

3171. Were they of a very painful kind?—Not at all.

3172. Was there so much of a painful character about any of them that it was necessary to employ anæsthetics?—Anæsthetics were employed in every one from first to last. I generally administered the anæsthetic.

3173. (*Lord Winmarleigh.*) Would they have been painful experiments without anæsthetics?—Most undoubtedly.

3174. In every case?—In every case; the operation consisted in the removal of the top of the skull, and the exposure of the brain, and in the application of electricity to the convolutions of the brain; the movements that resulted when electricity was applied in this way being carefully noticed.

3175. What was the duration of the experiment?—The longest lasted about six or seven hours.

3176. During the whole of that time the animal lived?—Yes; the animal lived, being kept constantly under the influence of chloroform. There were four or five medical men present, and one of them always gave his individual attention to the administration of the chloroform or ether.

3177. Were the animals killed immediately?—Immediately, either by pithing or by a poisonous dose of the anæsthetic, except in three cases where the hemispheres had been removed, and where the animals were kept alive for subsequent examination.

3178. In such a case it was supposed that there could be no feeling?—Yes, it was believed so; and these animals were kept alive to see the results. I should like to say that in the whole series of experiments resulting, as I believe, in an important discovery, the sacrifice of animals was 29, and of these five animals died before they were touched or operated on in any way from the effects of the anæsthetic, showing that it was carefully and liberally given.

3179. Was it generally known in the neighbourhood of Wakefield, amongst the medical profession, that you were performing these experiments?—Yes; the results were published afterwards in the medical reports of the asylum, and papers descriptive of the experiments have been read before the British Association and elsewhere.

3180. What were the class of medical men that attended your lectures?—They were all qualified medical men, my own colleagues and assistants in the asylum, with one or two medical men living in the neighbourhood, one being a member of the Society of Friends.

3181. Were any of your pupils present?—There were some generally present, but they were all qualified medical practitioners.

Mr. J. C. Browne, M.D.

26 Oct. 1875.

3182. These experiments then were not made with a view of instructing young men?—Not at all; it was with a view to discovery entirely. After the conclusion of the series of experiments, about six months afterwards, they were repeated upon two animals at a medical conversazione, attended by about 150 medical men, with the view of demonstrating the accuracy of Dr. Ferrier's statements, and of firmly establishing his novel and remarkable conclusions.

3182*a*. Do you believe that there are any other private laboratories except your own in which the same thing occurs? Are there experiments within your knowledge which have taken place in other parts of the country in such private laboratories?—I do not know of any such, except those performed in the great medical schools, the results of which have been published, for instance the vivisectional experiments of the Edinburgh Committee upon the antagonism of remedies.

3183. But you do not know of any other experiments outside the great medical schools, except your own?—I have not heard of any.

3184. (*Mr. Forster.*) With regard to those experiments there has been a controversy in the newspapers, has there not, between you and Mr. Jesse, the secretary of the society for the abolition of vivisection, and also between Dr. Ferrier and Mr. Jesse, as to how far there was chloroform given or not during the experiments?—I am not aware of any controversy; two or three letters passed, but we did not reply to Mr. Jesse beyond exposing his misrepresentations.

3185. I have had put into my hands (I believe it was sent to this Commission) a letter from Mr. Jesse in reply to a letter written by you to the "Times" on August 3d; his letter does not seem to have appeared in the "Times;" but it is a letter in which Mr. Jesse seems to wish to convey the impression that there could not have been complete chloroform administered; and you entirely deny that, as I now gather?—I do.

3186. You have not got the account of the experiment here in the publication of the Royal Society, have you?—I know nothing personally of Dr. Ferrier's work done for the Royal Society; I am only speaking of his first series of experiments performed at the West Riding Asylum.

3187. I think that this paper which has been sent to us alludes to the papers that were in the West Riding Lunatic Asylum Medical Reports?—I believe it does.

3188. If you turn to Mr. Jesse's letter, you will see that he states there that a cat "uttered long continued cries, screams, and gnawed its own legs, &c." Was that the case?—Quite so, that is quite correct.

3189. Will you explain how that was possible without its feeling pain?—The actions of the cat were mere mechanical movements performed during a state of profound unconsciousness. The animal, the top of the skull having been removed, was laid on a table; the electrodes were then applied to the convolutions of the brain; the animal would then move its paw as if striking a ball, open its mouth, twitch its ear, scream, or execute other actions according to the points touched; the moment the electrodes were removed from the brain all movement ceased. The animal was deeply narcotised by chloroform; the electrodes were again applied to the same spots, and the same movements were repeated; and so on with the whole series of movements—those of the tongue, arm, shoulder, &c. The cries of the animals under some of these experiments were no more significant of pain than are those cries which we frequently hear in the operating theatre when a patient is under chloroform.

3190. You have frequently given chloroform to human beings, I suppose?—Yes.

3191. Do you feel confident that in this case as much chloroform was given to deaden pain as you would have given in the case of a human being?—Yes, chloroform was given far more freely than it would be safe to do in surgical practice.

Mr. J. C. Browne, M.D.

26 Oct. 1875.

3192. Mr. Jesse says at experiment 3, on another strong cat, these words, "the animal was "only partially narcotised;" is that so?—That is quite correct. Absolutely deep narcosis, when an enormous quantity of chloroform was given, would approach so nearly to death that no movement would be elicited whatever. I may say that we know that chloroform acts first upon the sensory nerves, and long before unconsciousness comes on the pain has disappeared, as must be known to anyone who has inhaled chloroform for the relief of neuralgia.

3193. Immediately after that Mr. Jesse says, "on "another page we find the words 'with and without "'chloroform.'" It would be an unfair impression, would it, to deduce from that statement that any of the experiments were without chloroform?—I believe that in one experiment Dr. Ferrier was doubtful about a movement, and it seems the animal was allowed partially to rally from the deep narcosis in which it was; but in all the experiments at Wakefield chloroform was given continuously, or at intervals as occasion required, except in those three animals which were allowed to recover and live for several days, and in them, of course, the chloroform was not continued after the operation was over. The animals experimented on were never permitted to recover so far as to be capable of feeling pain.

3194. They were in the same condition as a human being who has had chloroform who lives after it?—Yes.

3195. (*Lord Winmarleigh.*) What is the nature of the establishment at Wakefield where this goes on?—The West Riding Lunatic Asylum, a large hospital having upwards of 1,400 patients.

3196. Not having for its object physiological inquiries?—No; but one of the objects is of course the treatment of mental and nervous disease; and these studies were undertaken to throw light upon the pathology of the brain and of mental diseases.

3197. (*Mr. Huxley.*) Will you allow me to read this first passage to you:—"Dr. Ferrier's asser-"tion that ether or chloroform was administered "before and 'throughout all' his 'experiments' is, "we believe, invalidated by the details which accom-"pany it. If ether or chloroform was administered "throughout 'experiment 4,' on a full grown strong "cat, and (as Mr. J. Crichton Browne's credulity "permits him to affirm, though it is what he cannot "possibly know) the creature felt no more than a "pianoforte, how was it the animal gave evidence of 'astonishment, anger, rage, and pain? How was it "the creature uttered long continued cries, screamed, "and gnawed its own legs, &c.?—the last a strong "manifestation of agony." Now of course on the face of this it looks a very powerful statement; but let me ask you, have you ever seen any cases of what is commonly called mesmerism?—I have.

3198. You have seen a person put into the condition of mesmeric sleep by the well-known operation? —Yes.

3199. And I dare say that you (as I have done) have, while the person was in that condition, tested the amount of sensibility he had?—Yes, I have.

3200. I dare say that you (as I have done) have passed a pointed instrument into the skin of the hand, or inflicted a severe pinch in order to be quite certain that there was not the smallest perception of sensation in that person?—Yes, I have, and to my knowledge operations have been performed painlessly under mesmerism.

3201. Nevertheless if you have seen the same sort of manifestations that I have, and I would ask you it you have, a person in that state may be made to perform the most singular actions—as, for example, to sing, to express the depths of bodily pain, to express hilarity, and to do a vast number of other things. Have you seen phenomena of that kind?—Frequently; repeatedly.

3202. And in fact they are exceedingly well established, and very common?—Yes; the phenomena of mesmerism and hypnotism are familiar physiological facts.

3203. And should be known to all well-informed persons?—Yes.

3204. So that in such cases as these anybody might argue, just as strongly as Mr. Jesse has done here, that it is inconceivable that the person who exhibited these phenomena should not be feeling at the time that he exhibited them?—Quite so; the cases are quite parallel.

3205. And yet you and I know perfectly well that when that person is awaked out of his mesmeric sleep he is absolutely unaware that anything has taken place; and, so far as we have any power of knowing, he has been in exactly the same condition throughout as a person under chloroform?—Yes; exactly. He seems to himself to have passed through a placid sleep, and is unconscious of having moved or suffered.

3206. (*Mr. Forster.*) But is it not also supposed by some persons that there is this difference between mesmerism and the influence of chloroform, that what happens during mesmerism is absolutely and utterly forgotten afterwards, and that there may have been sensations which disappear from the remembrance of the patient?—The same has been asserted of chloroform, but of course it is insusceptible of proof.

3207. But has it not been asserted more strongly of mesmerism?—It has been asserted of both, I believe.

3208. (*Mr. Huxley.*) I will now put to you a question in reference to the action of chloroform itself. I suppose you have seen many persons operated upon under chloroform?—Great numbers.

3209. It will be within your knowledge that persons differ almost indefinitely in the effects which chloroform has upon them?—They do.

3210. Some for example will become completely stupefied and lie like logs, and make no manifestation when the most severe operation is performed?—Quite so.

3211. And from that there is every gradation through the most violent movements, as if of pain, occasionally with groans and screams; and yet, however diverse these outward manifestations may be, the people in all these cases of administration of chloroform, are insensible to pain?—That is so. Persons under the influence of chloroform will sometimes smile and even laugh immoderately while actually undergoing the most painful operations.

3212. So that in your judgment the argument that is used in the passage which I have just read has no validity to any person who is acquainted with the effects of chloroform?—None whatever.

3213. (*Mr. Forster.*) I think I understood you to say that this action which appeared to look like the action of pain, such as the cat gnawing its own leg, was a sort of physical action induced by touching a particular nerve during the operation?—Yes. Might I just say that when the electrodes were applied to this point these movements took place; afterwards a red hot wire applied to the same point resulted in no movement whatever, but the animal lay perfectly still.

3214. (*Mr. Huxley.*) Is it not the case that in these experiments you may cause an animal while in a state of chloroform by touching particular parts of the surface of the brain to perform associated motions quite as complicated as those of biting its foot, each of which is associated with the mere superficial irritation of a particular region of the brain?—Yes.

3215. In fact you may play upon the animal as if it were a machine?—Exactly, as if it were a pianoforte when anyone is playing upon its keys.

3216. That is not done by touching the particular portions of the brain which, so far as we know would give pain, but by sending a comparatively weak electric current through a part of its superficial layer?—Yes, a current which Dr. Ferrier invariably tested upon his own tongue before applying it to the brain of the animal.

3217. So that it is not to be supposed that these motions are the result of doing anything which would inflict pain on the animal if it were sensitive?—That is so. I may mention that I have frequently had

Mr. J. C. Browne, M.D.

26 Oct. 1875.

cases of paralysis under my care where when you cut or pricked the foot it would be withdrawn as if with intense pain, and yet the patient would tell you he was not aware that his foot had been cut or touched. I should like also to add that these experiments on animals have been of great service to us already in enabling us to diagnose brain diseases; they have given us a new power of prediction as to them.

3218. (*Mr. Forster.*) They have been useful to you you mean, in your treatment of the insane at your Asylum?—Yes. I have been denounced for my own experiments, for the cruelty of searching by experiments on animals for an antagonist to pycrotoxine. There the operation consisted in the introduction under the skin of a little fluid by means of a perforated needle. It is an operation I have had performed on myself frequently; and of which the pain is infinitesmal. Then I was told that the operation was unobjectionable, but that violent convulsions were produced in the animal, and that these were painful and cruel. Now it so happens that this pycrotoxine is sold in large quantities as "Barber's poisoned wheat" for the destruction of birds, and numbers of animals die of it in convulsions every year, and I have never heard the sale of this wheat objected to or condemned. I may say also that convulsions themselves are not necessarily painful; although unconsciousness generally accompanies them, in a few cases consciousness remains, and in these cases we can ascertain the feelings experienced during the spasms. I had a patient lately under my care who during the fit used to say, "what a shocking bad fit I am having," and on asking her if she had pain she replied, "not any;" there was a feeling of wonder during the fit, and of muscular soreness and fatigue afterwards, but there was no pain in the convulsive movements themselves. We should desire, of course, to have protection in the performance of these experiments, because we feel that we are at present liable to annoyance by anyone who might choose to interfere with us.

3219. As you are the only holder of a private physiological laboratory I believe in this country, would you feel that any legislative inspection of that laboratory would be onerous to you, or in any way disagreeable or likely to interfere with the progress of science?—Not in the slightest degree. Inspection would, however, be impracticable, as there may be years together in which no experiments are going on. We keep for our own information a record of the animals destroyed.

3220. (*Lord Winmarleigh.*) You would not feel it any disgrace in any way to be under inspection?—No; inspection would be difficult, but we should wish to have some legal authority for what we might be doing.

3221. (*Mr. Erichsen.*) You would then feel that you were under the protection of the law?—We should feel that.

3222. (*Chairman.*) As far as you are concerned, I understand you to say that these experiments have been absolutely free from pain?—They have been free from pain.

3223. And that you have been subjected to the imputation that you were inflicting upon animals terrible pain?—Undoubtedly.

3224. And that a legal remedy which would secure you against being placed in what you consider an unjust position would be acceptable to you?—It would.

The witness withdrew.

Adjourned to to-morrow at 2 o'clock.

Wednesday, 27th October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.	THOMAS HENRY HUXLEY, Esq.
The Right Hon. W. E. FORSTER, M.P.	JOHN ERIC ERICHSEN, Esq.
Sir J. B. KARSLAKE, M.P.	RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

Mr. DAVID FERRIER, M.D., called in and examined.

Mr. D. Ferrier, M.D.

27 Oct. 1875.

3225. (*Chairman.*) I think you are professor of forensic medicine at King's College?—Yes.

3226. And also assistant physician at King's College Hospital?—Yes.

3227. We heard yesterday of some experiments which you had performed at Wakefield in regard to the examination of the various portions of the brain?—Yes, I made experiments at Wakefield on that subject.

3228. Were those experiments always performed under anæsthesia?—The method followed was to place the animal completely under chloroform, then to proceed to lay bare the brain by opening the skull, the animals being kept thoroughly under the influence of chloroform at the time, and during the whole of the subsequent operations, chloroform was administered intermittently in order to allay any movements indicative of pain on the part of the animal, or generally with the intention of preventing any suffering whatsoever.

3229. And do you believe that that intention was effectually carried out?—Thoroughly so.

3230. You have tried, I daresay, many other experiments?—Yes, I have performed other physiological experiments.

3231. Some of them painful in their nature?—Sometimes.

3232. But when they have been painful in their nature, have they always been under chloroform?—I think most of the experiments which I have performed have. I have some difficulty in recollecting all the experiments that I have performed for physiological purposes, but I have certainly always endeavoured to prevent unnecessary suffering in any animal upon which I did experiment.

3233. And may I take it that in the great majority of cases that endeavour has been successful?—I should say so, certainly.

3234. If I divide the subject of experiments into three parts, those which are properly called vivisectional, those which are upon the operation of poisons, and those which consist in the communication of disease to animals for the purpose of examining the progress and effects of the disease, dividing the subject into those three parts, and now asking you only about the first, is it necessary for any purpose of demonstration, in lectures, that the experiments should be otherwise than under complete anæsthesia?—Well, I think as to the great majority at least, of experiments for the purpose of teaching physiology, they may be

Mr. D. Ferrier, M.D.

27 Oct. 1875.

performed without causing the slightest pain to the animal under the influence of chloroform, or some anæsthetic. Practically, all experiments for demonstrational purposes of that nature are performed under anæsthesia.

3235. Then we may take it that for the purpose of demonstration experiments that fall under the head of vivisection are painless, because performed under chloroform?—I was endeavouring to think of any that are performed without chloroform, but I am unable to think of a single one.

3236. With regard to the second head, those that concern the operation of poisons, those I presume cannot be done under chloroform?—No, because that would interfere with the action of the poison itself.

3237. Now, are those experiments generally of considerable pain?—The experiments are of very short duration, because for purposes of demonstration the poisons that are used generally kill the animal within a very few minutes; as, for instance, the experiments with charcoal vapour, prussic acid, and strychnia, and poisons of that sort, which cause very characteristic symptoms, and which it is, I think, essentially necessary that students should see, so that they may be able to recognise the effects which these poisons produce in man.

3238. But they are rarely then you think, if ever, of any extreme amount of pain?—I think very rarely indeed.

3239. But is it ever the case that, for the mere purpose of demonstration to students, extremely painful operations are performed with poisons?—I have never seen any, and I should not care to do any such experiments myself.

3240. Then we may take it that as far as your practice and judgment are concerned, under that second head, namely, that of the administration of poisons, no very painful operations in that need be performed?—Nothing further than the injection by means of a needle underneath the skin, or into a blood vessel, of the poison; that is the physical pain to which the animal is subjected before the effects of the poison are produced.

3241. And, as I understood you, the effects of the poison are rapid, and there is no protracted agony?—No protracted agony.

3242. (*Mr. Forster.*) For instance, in the case of prussic acid the effect would be almost instantaneous?—Almost instantaneous.

3243. (*Chairman.*) Now, with regard to the third head, experiments in the way of causing disease for the purpose of observing its processes and its effects, is that ever done for the purpose of demonstration?—No, the very nature of the experiment itself makes it unsuited for demonstration; because to establish a disease is a long continued process, and in a lecture one can only do what is capable of being seen in a comparatively short period. The induction of a disease requires observation from day to day, to follow it in all its phenomena.

3244. Then, speaking of demonstrations to students only, at present we may say that those experiments which belong to vivisection may be entirely done under anæsthesia, that those which concern poisons are rarely painful and never involve protracted agony, and that those which concern the communication of disease have no application at all to the subject of demonstration to students?—I think I quite agree with that mode of putting it.

3245. Now, with regard to original research, how would you express yourself upon that subject?—I should say, that wherever it is possible to avoid the infliction of pain on animals subjected to experiments the means should be adopted, either by chloroform or ether or opium, or other anæsthetic; but that where the administration of an anæsthetic would prejudice the object for which the experiment was conceived, then the experiment is still justifiable, notwithstanding the fact that it might inflict a certain amount of pain on the animal.

3246. I understand you to imply, though perhaps you scarcely stated it in that answer, that the utmost pains should be taken to diminish suffering where it cannot be entirely avoided?—Certainly.

3247. In the great majority of experiments for original research is complete anæsthesia possible?—I think so, in the great majority of cases.

3248. Of the other cases, is there a large proportion where the most painful part of the experiment can be done under anæsthesia?—Certainly, all the operative part; the laying bare, for instance, of the organ which it is necessary to reach for purposes of experimentation; all that can be done under the deepest anæsthesia, and I believe, as far as I know of experimental physiology, is done so.

3249. With regard to the general tone of sentiment towards the lower orders of animals on the part of the medical profession in this country, and of the medical pupils in this country, are you able to speak to that?—I have never observed in any of my friends who have experimented on living animals, or in students or others who have seen such experiments, any indication of indifference to suffering on the part of animals.

3250. (*Lord Winmarleigh.*) Have you observed the reverse?—I have observed the reverse. Some of my friends, who I believe have performed as many experiments on living animals as most men in this country, are the most humane kind-hearted men that I know. I can mention several. I am perfectly convinced that experimentation on living animals does not tend to produce a want of sympathy with suffering, or to harden a man's nature in any degree.

3251. (*Chairman.*) Now, have you been consulted at all about the propriety of legislative measures upon the subject?—I have talked over the matter with some of my friends.

3252. What would be your judgment upon the effect of any measures which might restrain the progress of physiological investigation?—I think any legislation that would retard physiological research would be a discredit to this country.

3253. Suppose that there were any opinion that such experiments were resorted to by persons who were not possessed of the highest qualifications for them, would it be, in your opinion, any interference with the progress of science if such persons as those were restricted from trying experiments?—Well, I should say that it would be so extremely difficult to ascertain or to determine who were qualified, or to frame a standard of competency to make original research, that I believe legislation in that direction would be injurious.

3254. But supposing that the effect of any measures that might be proposed were to exclude ignorant and incompetent persons, without interfering with such persons as those to whom you have lately referred, would any objection in your mind apply to that legislation?—No, if a standard of qualification could be framed, which, however, I think would be exceedingly difficult. Indeed, it seems to me that it would be impossible to frame a standard by which it would be possible to test the competency of any man to perform experiments for the purpose of original research.

3255. Admitting it to be difficult, supposing that difficulty were overcome, would your objection be removed?—Yes, I think so.

3256. Is the number of persons in this country who do perform such experiments for the promotion of physiological science a great number?—Very few indeed.

3257. They are very well known, are they not?—Yes, I think so.

3258. They are men of great eminence, great reputation, and deserving the confidence of the country on the score of humanity?—Yes, certainly.

3259. But if other persons were to perform such experiments, it would perhaps not advance much the cause of science?—But a person often attains to eminence by making an original research before he is recognised as an eminent man; so that that is the first indication of his possessing the qualifications to rise to fame.

3260. The performance of the experiments by an ignorant or incompetent, or bungling person, would not conduce, I presume, to the advancement of science ?—Unless he were capable of appreciating and interpreting the true significance of the phenomena which were produced by his experimentation science would not benefit.

3261. And, of course, experiments in the hands of such persons would be very detrimental to the sentiment of humanity ?—I think they might be.

3262. (*Lord Winmarleigh.*) I understand you to say that you have no objection to some restriction being put upon unqualified persons experimenting in this way ?—I have no objection to a restriction being put on unqualified persons, provided you establish a sound criterion of the ability to perform experiments.

3263. But I presume that, according to the law of this country, even at the present moment, a person experimenting in surgery or in medicine without having the proper qualification, would be subject to that law ; therefore, there could be no reasonable objection in this branch of science which is so connected with surgery and medicine. Or would there be any objection on your part to a severe restriction against the practice of the examination of living animals by persons until they have attained some recognised qualifications for that purpose ?—Do you mean a medical qualification ?

3264. No. I bring forward the medical profession as an instance that the laws of this country will not allow anybody to practice medicine or surgery who has not established his qualifications. Is there any objection to the same rule being applied to the examination of living animals for the purposes of physiology ?—There is one case in which I should say it would operate injuriously, in the case, for instance, of a student of psychology who has no medical qualification, and who may wish to determine some question, say with regard to the nervous system, having sufficiently studied phsyiology and psychology as to be able to appreciate the results he would obtain by experimental research ; and I think such an one ought not to be restricted by any form of legislation which would confer this power only on medical men.

3265. Without any restriction would you have it ? —Without any on a man of that ability, I should say.

3266. But how would you test his ability ?—That is just my difficulty.

3267. But, supposing the same rule were applied in medicine and surgery, a man might rise to eminence in medicine and surgery by practising on his own foundation, without being under the regulations established by law ; would not the same rule apply to physiology when you have to practise upon living animals ?—If it were possible for this hypothetical individual to establish his qualifications before men who were competent to judge them, if he could establish his competency before them, then I should say he ought to be allowed to act without restriction.

3268. But you say you find great difficulty in that, and, finding that difficulty, I recollect from your evidence that you would allow everybody to practise experiments without any restriction by law or otherwise, because you say that a man often gets to eminence by the investigations which he makes in private ?—I believe that the absence of legislation would create no practical difficulty. Theoretically, every man may perform vivisectional experiments ; practically, very few do.

3269. Do you think that the law which is now in existence for the prevention of cruelty to animals is contrary to reason ?—Certainly not.

3270. You think that a proper law ?—I quite agree with it.

3271. But, under the circumstances which you have just stated, anybody whatever might practise any cruelty to animals under the plea that he was making experiments in vivisection ?—Well, I suppose under the present act each case would have to be judged on its own merits.

Mr. D. Ferrier, M.D.

27 Oct. 1875.

3272. Should you, as a practical physiologist, consider it any stigma upon yourself to have some limitation put upon the practice of these experiments ? Should you object to a law which stipulated that these experiments should be performed under some limitation, either of inspection, or in some other manner ?—I should certainly object to inspection of any kind in my experiments. I think it is possible that the method which has been suggested of giving a license to those who are qualified to perform experiments, a license simply, without any inspection or the necessity of keeping a record, would not interfere to any great extent with the development of original research, which, I think, ought to be encouraged in every way rather than restricted.

3273. You are, on the whole, of opinion, as I understand, that the practice of research by experiments on living animals should be open to the public without restriction ?—Well, I think, owing to the great agitation that has taken place in the public mind so recently, it is very desirable to distinctly dissociate experiments for the purposes of original research from cruelty to animals, or the law which punishes cruelty to animals. I think that the two are totally different, and that experiments for original research do not come in any shape or form under the provisions of the enactments against cruelty to animals ; but, as the popular mind has been so excited in regard to this subject, I think that some legislation, in which a clear distinction should be drawn between the two, would be advisable.

3274. (*Chairman.*) Your attention has been called to the evidence of the Secretary of the Royal Society for the Prevention of Cruelty to Animals ?—Yes.

3275. Have you any observation to make upon that evidence so far as it affects yourself ?—I am ignorant of what he alludes to, or of any expressions that I may have used which would justify his criticisms. I gave a lecture on the functions of the brain before the London Institution (I think that was the lecture he referred to), in which I described the effects produced by applying electricity to certain parts of the brains of the lower animals ; but I am not aware of having described them with any degree of levity, such as he charges me with ; and if, for instance, I stated that the application of the electricity to a certain part of the brain of a dog made him wag his tail, that may have appeared ludicrous, but I am unable to see how a statement of this fact can be construed into levity on my part. The monkey under the stimulus of electricity, makes in a state of unconsciousness a number of grimaces and movements of its arms and legs. These may appear very laughable to some persons, I myself cannot see anything laughable in them, and beyond that I am utterly unable to understand to what he refers.

3276. I think I may say that any charge of indifference to suffering was altogether disavowed by the witness ; but the committee of the society brought under our notice certain remarks, particularly upon the monkey, which you are said to have made at that lecture. Referring to the answer to question 1576, do you entirely disavow the statement that "the whole lecture place was really like a comic scene," and that three gentlemen were there who were members of the committee of the society for the prevention of cruelty, "and two of them left the room in disgust ;" do you know anything about that ?—I certainly do not. The effect I observed on the audience was an intense desire to listen to me as long as I would go on. I kept them half an hour or three quarters of an hour beyond the time I had stipulated ; some of them had to leave to catch their train, but the attention generally was most intense and continued during the whole time of the lecture. I saw nothing comic in the matter, nor did I see any levity on the part of the audience, and there was certainly none on my part.

3277. Do you entirely disavow any notion that animal suffering was the subject, either on your part

Mr. D. Ferrier, M.D.

27 Oct. 1875.

or on the part of the audience, of anything approaching to a joke ?—Entirely.

3278. The animals that you were speaking of in your lecture were animals which had been the subject of a former experiment ?—Yes, of a former experiment, not of any experiment I was performing at the time.

3279. (*Mr. Forster.*) Were the audience informed that the experiments which you had conducted, and which you were describing to them, were conducted under anæsthetics ?—I think so ; I have always done so, so far as I recollect, in my lectures.

3280. Then you consider that it would be a most unfair impression that anybody could take away from your lecture that you were describing to anybody the sufferings of animals in a way that should induce them to laugh at them ?—I certainly think it would be a most unfair misrepresentation.

3281. (*Mr. Huxley.*) A question was put to the secretary of the society mentioned as follows,—at No. 1588, "Then the laughter which it induced may " have been from the inherent grotesqueness of the " thing, and not from any desire of Dr. Ferrier to " make it grotesque ?" And the answer was " Yes, " but the skill of the lecturer was used to cover the " grim character of the experiment by his humour." Have you any observations to offer upon that statement ?—It is a very extraordinary statement. The "character" of the experiment may have seemed "grim" to him, but I am not aware that I lectured with any degree of humour ; it is a sort of thing that I do not claim credit for, at least, in my lectures. I was trying to describe in plain language the simple results of my experiments.

3282. Although it is a trifling matter, and one that I am almost ashamed to trouble you about, may I ask as a matter of fact whether you yourself laughed during the description ?—I should say I did not.

3283. You had no desire to give what is called a sensational lecture ?—No.

3284. You had very important facts to put before your audience, and you put these facts before them to the best of your ability ?—That was all.

3285. (*Sir J. B. Karslake.*) Might I ask you, following that up, how long ago was this lecture delivered ?—Last spring ; I think in the month of March.

3286. Where was it delivered ?—At the London Institution, Finsbury Circus.

3287. And was it delivered before a mixed audience ? —Delivered before a popular audience, the subscribers to the institution.

3288. Amongst those there may have been many who were not medical men, or connected with the medical profession in any way ?—The great majority were not.

3289. If I understand you, you were describing the effects of electricity upon animals when in a state of anæsthesia ?—Yes.

3290. Did you speak from notes ?—I think not.

3291. Is there any journal which has been published to your knowledge which gives an outline of your lecture ?—I have never seen one. The lecture was essentially the same as that delivered before the British Association at Bradford, and delivered in the same manner.

3291*a*. Can you at all recollect the terms in which you described to the audience, the gesticulations or the grimaces of the monkeys and the dogs ?—The way in which I described them was simply this : I had diagrams before me, and with the pointer I would point to a certain part of the brain, and say, " When I apply the " electrodes to this part of the brain the animal will per- " form such and such an action ; for instance, it will " open its mouth, wag its tail, or stretch forward its " leg," and I described generally the actions caused by the stimulation of each individual part of the hemispheres.

3293. Now, whatever effect it may have produced upon the audience, were you conscious at all of having gesticulated or imitated the contortions of the monkey, so as to cause a laugh among the audience ?—I am not aware of it.

3294. Had you any intention of doing so ?—Certainly not.

3295. Had you any remonstrance from anybody about the lecture ?—Certainly not. This is the first time I have heard of any exception being taken to it.

3296. How long have you been a lecturer to classes ? —For the last five years.

3297. Have you used demonstration upon living animals in a state of anæsthesia, and sometimes when they were not in a state of anæsthesia, all that time ? —No, not all that time. In 1870 I lectured on physiology at the Middlesex Hospital, and I did not perform any experiments there ; but a year afterwards I went to King's College, to become demonstrator of practical physiology. It was then my duty to perform what are called the fundamental necessary operations and experiments, for the purpose of instruction of the students ; as, for instance, to show the laws of the physiology of the circulation ; but in all these cases we give anæsthetics.

3298. About what is the number of your pupils in the class ?—I lecture to a class varying from 40 to 50.

3299. May I ask you, in your judgment, is it essential for the due teaching of those students that they should see these demonstrational operations ?—I think some of them are absolutely essential for proper instruction. I am at present professor of forensic medicine, which includes the whole subject of toxicology, and in this I think experiments are absolutely necessary, in order that the students may recognise the characteristic symptoms produced by some of the more active, and most commonly used poisons, and also that they may see the methods by which we may counteract these, the methods of administering antidotes, and the method of restoring suspended animation in animals that have been asphyxiated by carbonic acid, or those gases that paralyse the respiratory function. All these, I think, are exceedingly important, and some of the effects are physiological tests for poisons themselves. For instance, there are some poisons, such as digitalis, which gives no very definite chemical reaction, but which has a very distinct effect upon the heart of the lower animals ; and that is a test by which it is distinguished. Such tests have been employed with the sanction of Government in prosecutions against poisoners, often establishing important evidence, which could hardly have been ascertained by any other method.

3300. Have you yourself been engaged in experiments which, as you say, have been sanctioned by Government as experiments on living animals for the purpose of ascertaining the effects of poison ?—I have not.

3301. Do you know of cases where scientific men have been so engaged ?—Certainly.

3302. And where they have had to make experiments on living animals for the purpose of ascertaining the effect of poisons with a view to bringing criminals to justice ?—Certainly.

3303. You have spoken particularly about these experiments which are made before a class, or some portion of a class, in reference to poisons. In your opinion, could the knowledge which is obtained by them from the exhibition of animals under the influence of these poisons be effectually obtained from reading or description ?—I think not ; it could not be effectually communicated by any oral instruction.

3304. You have stated your objections to legislation with reference to any licensing of persons who should make these experiments with a view to research in physiological subjects. In the medical profession, for physicians and surgeons, there are examinations in order to test their ability before they are permitted to practice ?—Yes.

3305. Is there any such examination at the present time in order to ascertain their knowledge of physiology ?—Not specially ; it is only part of the medical examination.

3306. Then it would be necessary to have some examination to ascertain the competency of any particular person, if the license in this case was to be

Mr. D. Ferrier, M.D.

27 Oct. 1875.

founded upon any special knowledge?—It would require a special examination.

3307. (*Lord Winmarleigh.*) Does physiology form a part of the examination for medical men?—Yes, one of the most important parts of the examination.

3308. Universally?—Yes.

3309. (*Sir J. B. Karslake.*) It forms part of the examination, but the power of manipulating and carrying out these things by experiments on animals is not tested in any way, is it?—No.

3310. Then, for the purpose of granting a license, founded upon special knowledge of the mode of experimenting upon animals with a view to physiological research, there must be some examination and diploma which does not exist at the present time?—There must be, if it is considered necessary to license those who make such experiments.

3311. In your opinion, would a simple license to a person who wished to carry out this sort of research, founded upon the certificate of persons in whom trust might be placed, in any way interfere with the study of physiology?—I think it would be objectionable, but I think it is the best compromise in the case. I should not like it for my own part, but I would rather submit to it than that there should be any further interference with experimentation on living animals for purposes of research.

3312. (*Mr. Huxley.*) You, as a medical man, are doubtless acquainted with the state of the law regulating medical practice. Am I right or wrong in supposing that in the present state of the law there is nothing whatever to prevent a man from practising surgery or medicine, if he likes?—I think that is so.

3313. A document has been laid before us which is said to have been prepared under the sanction of the Society for the Prevention of Cruelty to Animals, and is addressed to us; it is a very formal document, and at the end of that document it is stated, as evidence of the "growing carelessness" with regard to the sufferings of animals in this country, that "popular "lectures were being given, of a sensational character, "by a learned professor, who made his audience laugh "over the grim behaviour of his unfortunate victims." Now, I suppose that if any person could have been shown to do that, no one would be more ready than yourself to say that his conduct was unworthy, not only as a man of science, but as a man, and wholly worthy of condemnation?—No one.

3314. From what you have heard, you will gather that the sole foundation for this official statement that has come before us is the allegation made by the secretary and others with regard to your own lecture; but I understand you to absolutely and utterly deny that there is even a shadow of foundation for that statement?—Entirely.

3315. Was the audience on the occasion on which you addressed it a large one?—It was an audience of 200 or 300 persons.

3316. Was the theatre of the institution full?—Pretty nearly.

3317. On occasions of that kind, when important lectures are delivered, it commonly happens that the managers of the institution are present?—They were present on that occasion; I gave two lectures, and they were present on both occasions.

3318. You are aware that the managers of the London Institution are gentlemen of high standing and character?—Certainly.

3319. And yet I gather from what you have said, that no one of them made any remark to you, even privately, upon the subject upon which you have just been questioned?—No one; they were extremely anxious that I should lecture again that very season, and they have asked me to lecture this year again.

3320. You have heard a plan suggested for inspecting physiological laboratories?—Yes.

3321. But I understand you to express a disapprobation of it?—A very great disapprobation of it.

3322. Will you state your reasons for your disapprobation?—In the first place, one would be prevented from performing experiments without having to write and give an intimation that such and such an experiment was to be done. Perhaps, after all, the experiment might turn out to be unsuccessful; and there would be so much trouble thrown in the way of doing anything that I believe most experimentors would rather refrain from work than be at the trouble of summoning the inspector on all occasions on which they wished to perform experiments.

3323. And I presume that as a man of science, knowing what investigation is, and being well aware that even among men of science, very few, except those who are engaged in a special inquiry, are really competent to judge of its value, you would view with some trepidation inspection even by competent men of science?—I should.

3324. And supposing that the other alternative which has been presented to us were adopted, and that the persons who were made inspectors were simply, I do not like to use the word laymen, but I mean persons not accomplished in physiological matters, do you think it likely that they would report on such cases with more fairness and understanding of what was going on than the official representative of the very important and useful body, the report of whose committee I have just read to you?—I should say they would be extremely incompetent to give a correct account of the results of experiments.

3325. In fact the sort of report which I have just read to you does not fill you with any great comfort at the prospect of what I may call lay inspection?—Not at all, exactly the reverse.

3326. (*Mr. Erichsen.*) Would you see any objection to places being licensed? We have spoken hitherto of inspectors, and inspection of actual experiments; but would you object to places being licensed in which experiments might be performed, say physiological laboratories, throughout the country, and merely subject to that general sort of supervision that the inspector of anatomy exercises over a dissecting room?—I should object. I should allow everybody liberty to perform experiments in his own private laboratory. A great many experimentors live in the country, and have no access to a public laboratory, and that would entirely prevent them from carrying on research.

3327. Do you think that there are many such persons?—Yes.

3328. And who are practising in their own laboratories, and unconnected with medical schools, do you mean?—I used to do so when I lived in the country, in Suffolk, at Bury St. Edmunds. I performed experiments there for my own purposes of research.

3329. I ask that question because hitherto we have not been able to hear of any such laboratories, or but very few. Do you know of any, or could you give the Commission the names of any gentlemen known to you who are practising in their own laboratories in the country?—The private laboratory at Wakefield is one, and it is one where a great deal of exceedingly good work is being done. I know that particularly well; and though I am not acquainted with any one at present who is carrying on physiological research in the country, because, of those who are doing so, the great majority are attached to schools, either in London or some of the provincial towns, still I may say that I prefer to do experiments for original research in my own laboratory.

3330. But your own laboratory is at King's College, I suppose?—No, at my own house.

3331. Then you experiment at your own house as well as at King's College, do you?—Yes; it would interfere with my professional work if I were obliged to go such a distance from home to perform my experiments.

3332. You have been connected for some time, I think, with King's College?—For two or three years.

3333. And you are consequently a colleague of Sir William Fergusson?—I am.

3334. Now, we have had it in evidence from him, that for the purposes of experiment, (and I will take the exact words, they occur in the answer to question

Mr. D. Ferrier, M.D.

27 Oct. 1875.

1037,) that animals are "crucified sometimes for several days," and introduced several times during that period into a class for the purpose of observation?—I certainly never heard of such a thing.

3335. I would ask you, as one of the professors at King's College, whether such practices are ever, to your knowledge, carried on at King's College?—I know they are not.

3336. As a physiologist, and one, as we know, extremely well conversant with what is going on at the present day, more conversant at your age probably than older men often are, are you, to your knowledge, aware that such practices are carried on in any part of this country?—I should say they are not.

3337. Have you ever heard it?—I never heard of such a thing.

3338. That an animal is crucified and introduced several times in a state of crucifixion to a class for observation?—I am quite sure no such things ever occur in this country.

3339. Do you believe that any student would tolerate such an exhibition in this country?—I think not.

3340. We heard the other day from a very distinguished physiologist who has lectured for 20 years in London that he would not venture to exhibit a painful experiment without anæsthesia to his class, because it would be repugnant to the feelings of his class?—It would be so, decidedly.

3341. Is that your experience with regard to the students in London?—My experience with regard to students is this, that even when the animals are completely under anæsthetics, there is always a feeling of repugnance to experiments, similar to that which is felt to the first surgical operations.

3342. And that it would be more repugnant to them if it was without anæsthesia?—Certainly.

3343. And it would be extremely painful?—And I believe they would rebel.

3344. That a teacher, in your opinion, would not venture to submit such experiments to his class?—I should not do so myself, and I do not know of any other teacher who would.

3345. I received last night a paper headed "The Moral Aspects of Vivisection," written by Miss Frances Power Cobbe, and you are the first witness that I have had an opportunity of putting this question to. I should have preferred putting it to some one older, but as you have had considerable experience in two London schools you will be able to answer it. I find in this document the following statement: After speaking about students trooping out to see an animal killed, it goes on to say, "The "same keenness of observation or a memory of their "own youthful insensibility ought to teach all pro- "fessors of physiology that they are indulging a "maleficent tendency which already exists in their "pupils' disposition when they invite mere lads of "the Bob Sawyer type to watch their frightful "experiments, the more frightful, so much, alas! the "more attractive." Now, I would ask you whether, as a teacher of physiology in London, you find that, in the first place, the medical students as a body have "maleficent" tendencies?—Certainly not, from my experience.

3346. I would ask you whether it is not the fact that in most of the London medical schools there are young men's Christian Associations?—In many of them.

3347. Is there one at King's College?—I am not sure. I know that there are at Edinburgh.

3348. There are in London; and it being the fact that in London there are these young men's Christian Associations connected with the medical schools, is it also the fact that there is a united young men's Christian Association of the London medical schools?—I have heard of such.

3349. And do you think that the students who belong to that can be characterised as having "maleficent tendencies?"—I should say not.

3350. Is it not, in your opinion, a gross libel upon a class to stigmatise that class as having "maleficent tendencies?"—I certainly think it exceedingly libellous.

3351. Then, according to your experience, will you tell me whether experiments are more attractive the more frightful they are; I will quote the words, "the "more frightful, so much, alas! the more attractive"?—I have never seen any indication of such a thing; in fact I have never seen any frightful experiments of any kind.

3352. I was just going to ask whether any experiments of a frightful character are performed before students?—They are not, as far as my experience goes.

3353. Is it the fact that experiments for demonstrational purposes are constantly performed under anæsthesia?—They are performed under anæsthesia.

3354. Would it be prudent, in your opinion, for a teacher of physiology to perform a "frightful" experiment before his class?—It would not.

3355. The class, as you have already said, would probably rebel?—They would.

3356. And therefore you do not believe this statement, and that it is entirely inconsistent with everything that you know of medical students that "the more frightful the experiment the more attractive" it is?—It is certainly inconsistent with anything that I have seen of the character of medical students in any schools with which I have been connected.

3357. Either in London or in Edinburgh?—Either in London or in Edinburgh.

3358. (*Mr. Hutton.*) With regard to that matter, to which some reference has been made in Mr. Colam's evidence, about your lecture, I see this statement: "I have heard him say" (that is referring to yourself) "that the animals appeared to be in intense "suffering, and then joke about the stupidity of the "animal, especially if the animal happened to be a "monkey;" and further on I asked a question on that subject, and said, "May I ask you to explain "your statement that the lecturer joked about the "stupidity of the monkey. Those movements were "involuntary, were they not?—Of course they would "be," Mr. Colam replied, "because he showed that the animal had no volition at all." Do you recall the words about the "stupidity of the monkey" at all; that those words were used by you, or were capable of causing a laugh at the time?—I cannot think of anything that I said to which such a criticism would be applicable. Perhaps I may have stated the fact that certain lesions of the brain produce special effects on the intelligence.

3359. Which look as if they were stupid?—They may make the animal appear stupid, or produce a state of dementia, as I should call it; but I cannot recollect anything I said which could be construed into making such condition the subject of a joke, certainly not if the animal had exhibited the slightest suffering.

3360. I have been told that in the same lecture you stated that you were afraid to say on how many cats you had made the same experiment, and that that statement caused laughter in the audience. You have already said, I think, that you saw no laughter in the audience; but do you remember whether you did make that statement, that you were afraid to say on how many cats you had repeated the experiment?—I certainly should not be afraid to say it. I have no recollection of making any such statement. As far as I remember, when I described my experiments at the British Association at Bradford, I stated distinctly the number of experiments which I had made.

3361. How many were they?—About that time altogether I stated that I had experimented on about 100 animals, taking them all in all; and I do not think that I should be afraid to state at the London Institution what I stated publicly before the British Association.

3362. And you were not aware that any laughter was caused by that, or any other statement?—I observed none.

Mr. D. Ferrier, M.D.

27 Oct. 1875.

3363. I have before me an article of yours on "Experimental Researches in Cerebral Physiology and "Pathology in the West Riding Lunatic Asylum "Medical Reports;" you say in the beginning of this article, "It may be mentioned here, once for all, that "before and throughout all the following experiments "æther or chloroform was administered;" but then there are many traces throughout the article that you yourself believed that the animal was not under anæsthesia in a great many of these experiments?—In regard to the administration of chloroform, I may remark that chloroform must be administered intermittently; the continuous administration of chloroform must inevitably cause death. Chloroform is being administered throughout the whole of the experimentation, but it is kept up in such a manner as not to endanger the life of the animal; sufficient chloroform is given, however, to keep it narcotised to such an extent as to abolish all consciousness of pain.

3364. However, I suppose you not only admit, but maintain, that in a great many of these experiments a great deal of pain was caused, owing to the interruption of the chloroform?—I think I saw no indications of the animal suffering pain.

3365. But you have expressed yourself so in this article as to many cases. At page 79, for instance, I see you say, "In order to determine whether the "combined movements were conditioned by the "voluntary impulse of the left hemisphere, I next "proceeded, two hours after the removal of the right "hemisphere, to expose the sigmoid gyrus of the "superior external convolution of the left hemisphere. Having ascertained by electrisation that I "could induce the usual movements of the right fore "leg by stimulation of its centres here situated, I cut "away the greater part of this gyrus, checking the "hæmorrhage with cotton wool steeped in perchloride of iron. After this the animal ceased to "struggle, and lay in whatever position it was placed. "Pinching the toes caused reflex movements in all "the four limbs, and at the same time the animal "barked energetically and howled when pinched. "Pinching of the tail especially caused the animal to "bark. This condition continued for several hours, "barking being always elicited and some reflex movements of the legs, but not to any great extent. The "barking may also have been a reflex phenomenon, "but from the fact that barking alone was sometimes "induced without any marked reflex movements of "the limbs, I was rather inclined to attribute the "phenomena to retention of consciousness and "distinct sense of pain. Ultimately (five hours after "the first operation) no barking was caused, but only "reflex of the limbs and trunk when the legs or tail "were pinched. The dog survived for eight hours "after the removal of the hemisphere." In that case clearly you did believe that the animal was suffering?—My last answer was with reference to the experiments on the electrical excitation of the brain, and that one which you have now read I had not in my mind; and even there I had very considerable difficulty in determining whether the animal was conscious or not.

3366. Still your opinion was that it was conscious?—That was the opinion to which I came in the end.

3367. Then at page 36 you say, "After 40 seconds "the right lip began to twitch; in 55 seconds, "twitching in the right forepaw; in 1 minute 10 "seconds, right lip twitching violently and jaws "working; in 1 minute 30 seconds, head drawn "over right shoulder; in 1 minute 46 seconds, the "fit stopped suddenly, and animal appeared to wake "up from a state of stupor." Then, I suppose, the pain began again, did it not?—No, certainly not; not even during that convulsion did the animal experience the slightest pain.

3368. Not even when it "woke up from a state of stupor?"—It falls into the epileptic coma, and you see a resuscitation after that, but not to pain.

3369. Then on page 38 I read, "The head was "immediately turned to the right, but it was doubtful "whether the movement was spasmodic or voluntary, "as the animal was only partially insensible." There, I suppose, there was a chance of pain?—It was sufficiently narcotised to abolish any real pain.

3370. That is hardly the impression that I think the language would give to anyone reading it for the first time?—I think that the phenomena known to all surgeons, which are manifested by human beings under chloroform, are quite consistent with these experiments being carried out altogether without any consciousness on the part of the animal.

3371. Here again, on page 42, it is stated, that "The animal exhibits signs of pain, screams, and "kicks with both hind legs, especially the left." Would you have used the expression "signs of pain" if you had simply meant reflex actions?—Yes, because I may stimulate the apparatus which gives the external manifestation of pain without inflicting pain on the animal.

3372. Here again, on page 44, I see this, "Restlessness, opening of the mouth, and long continued "cries, as if of rage or pain"?—There I put in the words "as if" because I did not believe that they were so in reality.

3373. That is why I assume that in the cases where you do not use that expression you did believe that pain existed?—If I did convey that impression it is certainly not the impression that I wished to convey in my remarks.

3374. However, in that first case that I read the account of, you did believe that the animal was suffering apparently?—Yes; that was an experiment which was performed in the only possible way of ascertaining the function of a certain part of the brain; and it is an experiment which does not require to be repeated when the fact is once established.

3375. (*Chairman.*) Is it the case that in severe surgical operations performed upon the human subject there are not unfrequently all the usual demonstrations of pain in cases in which, when the patient recovers, he or she says that they have experienced no pain?—That is a matter of every day occurrence, and quite familiar to all surgeons; and particularly it is the case in the administration of chloroform for obstetric purposes; in these, it is not carried to complete anæsthesia, but sufficient to annul any sense of pain; so that I have seen patients in this condition of anæsthesia manifest the signs of pain, screaming, groaning, and bodily contortions, who afterwards have told me that they have had a pleasant dream all the time, and never experienced the slightest pain during the whole period.

3376. (*Mr. Hutton.*) What particularly impressed me in that experiment of yours which I read first was a part of it which I did not read just now. At the beginning, page 78, you say, "It retained the power "of opening both eyes and of howling and barking in "a very vigorous manner. Apparently it remained "quite conscious, for, when called to, it would "struggle to get up, and would sometimes regain its "feet, and even succeed in walking a few steps, "when it would fall over in a helpless manner." That belongs to the first experiment which I read. Now did not that indicate complete consciousness so far as the experiment went?—It would indicate consciousness, but I think there is nothing there to indicate that the animal was in suffering.

3377. But if there was consciousness I suppose that anything which would ordinarily cause suffering would cause suffering then?—Yes, but I saw no indication then that the animal was in pain. We know that men may have part of the skull removed and yet not complain of the slightest pain.

3378. In experiment three on a strong cat you state that "the animal was only partially narcotised," and you speak of the experiment being "with and without chloroform?"—My attention has been called to that expression, "with and without chloroform;" and you will see, if you read the sentence, that it stands "with and without chloroform no effect was

Mr. D. Ferrier, M.D.

27 Oct. 1875.

produced," no pain or indication of pain being manifested; and it was necessary, in reference to the question of the excitability of the cerebellum, to ascertain whether the absence of effect was due to anæsthesia or not; you will see that there is complete proof that the animal was not suffering in the slightest degree.

3379. Not this dog on which the experiment was tried?—This dog I believe was not suffering.

3380. Surely you express your view that it is, at the end, do you not?—I made an experiment there to ascertain if the animal was conscious.

3381. You also said you would incline yourself to the belief that there was a sense of pain?—I pinched its tail in order to ascertain whether it was conscious, just as I might pinch a man's ear; but when I obtain a proof of the consciousness I inflict no further pain upon the animal.

3382. All this is mere conjecture, is it not; it leads you to hope that it is not suffering, but you cannot tell whether it is suffering or not?—I think we can; I think we have distinct facts to show that in well known cases of injury to the brain.

3383. (*Mr. Forster.*) Did you administer chloroform with the intention of preventing these animals from suffering during these operations?—Certainly, always.

3384. You have been in the habit of administering chloroform to human patients?—Yes.

3385. Did you in these cases administer it in the same quantity, and in the same careful manner, as you would have done if you had been performing an operation on a human being?—Certainly, and my difficulty was to avoid giving the animal too much, for I frequently, in seeking to keep the animal unconscious, lost the animal, it died from an overdose.

3386. That means that you gave them more chloroform than you would have done with a human being, because with a human being you would have been afraid of death following?—Yes, and one requires to be exceedingly careful in its administration; and I have frequently had, in the middle of my operation, to resuscitate the animal from the effects of poisoning by chloroform, from administering the chloroform too continuously. It requires to be given with exceeding care, so that the respiration may not become paralysed.

3387. (*Mr. Hutton.*) As to the results of all these observations, is it not the fact that it is a question in dispute between you and the German physiologists, whether your results are correct?—I believe that all new doctrines are received with adverse criticism at first. I believe that the main results are accepted by all physiologists though there may be differences as regards interpretation.

3388. We were told not long ago that the functions of the brain are so much the same in the human beings and the lower animals that it is not necessary to verify, even for scientific purposes on human beings, results obtained on the brains of the lower animals. Is that your opinion or not?—I think before a result which is obtained by experimentation on the lower animals is to be accepted as applicable to human beings it ought to be determined whether it is in harmony with the facts of pathology, so far as we know them; but when the data of human pathology indicate the same facts as we obtain by experimentation on the lower animals, we are enabled to arrive at a rational explanation of them.

3389. I noticed that at the Edinburgh meeting lately very considerable doubts were thrown on your experiments, on the ground that they were not made upon beings near enough to man; I think it was M. Dupuy who expressed those doubts, was it not?—As far as I recollect it was by a man who has no standing at all, a practitioner in the country, not conversant with physiological subjects. It is a well known fact that the organization of the monkey's brain is almost identical with that of the human brain, and that what is true of the monkey is true of the human being.

3390. Is it not within your knowledge that the same experiment has been tried in America on a human being with the view of testing the applicability of these experiments to the human being?—I believe such an experiment was performed in the case of an Irish servant, who, from ulceration, had a large part of the brain exposed; and the American physician, thinking that irritation might be applied to the human brain with the same degree of safety as to the brains of the lower animals, applied electricity to ascertain whether similar movements would be induced in her as in monkeys; and he found that that was the case. The woman afterwards died, some said, from the result of his experiments; I believe, however, that the woman was in a very perilous condition at the time, and the post mortem examination showed that she had died from the results of the disease.

3391. I think the opinion was that he had hastened her death, was it not?—It may have been so; but without all the data we cannot pronounce definitively upon it.

3392. I mentioned that because you said that you entirely objected to anything which would restrict physiological research; of course you did not mean to include the rights of human beings in that statement; you would strongly object to physiological research on human beings?—Certainly.

3393. Do you not think that to a certain extent the sufferings of animals are considerable enough to be counted as deserving a certain proportion at least of the weight which you would attach to the sufferings of human beings; that there are in fact physiological results, which one would rather sacrifice than attain them by these exceedingly painful experiments; I gather you do not think that?—I think we are in need of every additional fact to advance the science of physiology, and physiology as a science can only be advanced by the accumulation of facts by different experimenters. Although the result obtained by any one individual may not appear to be of great importance, yet for the whole science it may prove of great importance, and it is only in this manner that science has reached its present state of development.

3394. The logic of that reply would lead you to make similar experiments on the human being; that you entirely disavow. I ask, do not you consider that the sufferings of animals are sufficiently important as compared with the sufferings of human beings, to make it often desirable rather to sacrifice a physiological truth than to inflict all these sufferings?—No, I do not see that the sufferings of animals are so very great as compared with human sufferings.

3395. I was particularly struck by your saying that you really would rather allow a psychologist, who might be a bad physiologist, to experiment in a way that might torture an animal extremely rather than sacrifice the results which he might gain as a psychologist by those experiments. Surely that is a sacrificing of animals altogether?—I did not suppose that a psychologist would be so ignorant of the subject as to go in a bungling way to work; because, so far as I know the psychologists of the present day, they are well acquainted with the practical results of physiology.

3396. One would be very sorry to trust a psychologist, who was not a good physiologist, with experimenting on one's own brain?—Well, I do not know any experiments on the human brain.

3397. He might, for instance, make, on the human brain, the experiments that you have made on the brains of animals?—I entirely disavow any experiments on human beings; and it is for the purpose of saving human beings suffering that we make experiments on lower animals.

3398. But you go further, and say that you would allow incompetent men to experiment on the lower animals, so long as they had psychological objects n view?—That is not my meaning.

3399. You objected to restriction, on the ground that it might prevent some psychologists from so experimenting?—I only said that I objected to re-

Mr. D. Ferrier, M.D.

27 Oct. 1875.

striction, of such a kind as might interfere with men capable of research; and I thought that by taking the standard of medical qualification you would interfere with men capable of performing such experiments.

3400. But you would also interfere with men who were capable of giving a great deal of unnecessary pain?—Practically, we find so few people in the country who make experiments of this nature that I think we may trust the good sense and humanity of the great majority of mankind not to make experiments unless some good can be got by them.

3401. As to poisons, do you find it necessary to experiment for demonstration on almost all of the strongest poisons?—I do not experiment with all; but some of them are so characteristic in their effects, and it is so necessary that students should see them, that I make experiments with them. For instance, I make experiments with charcoal vapour, which sends the animals very quickly to sleep, and they die in a state of asphyxia; but there the condition of the animal after death is so characteristic that it cannot be described, it must be seen.

3402. That is not a painful experiment?—No. Then, too, I experiment with strychnia.

3403. That is a painful experiment, and it is one of the most painful deaths, is it not?—The convulsions are rapidly over. It is said to cause a considerable amount of pain during the convulsions; but we experiment chiefly on frogs with strychnia, and their consciousness of pain is not very highly developed I think.

3404. You do not experiment then on any mammals with that poison?—Yes, with rats and mice, and sometimes with birds, and sometimes with rabbits and guinea-pigs.

3405. You do not use more painful poisons than any of these in demonstrating experiments?—No, I only use those which rapidly kill the animal.

3406. (*Mr. Huxley.*) In some of your experiments, after describing your operation upon the anæsthetised animal, you go on to say that on a certain stimulus being applied the animal showed signs of pain. I apprehend from some of your answers that what you meant to say was that the animal exhibited the same kind of motion as it would exhibit if it were in pain? —Exactly, that is what I meant.

3407. But I apprehend, also, that it may be possible (I should like to know whether in your judgment it is possible) that in some of these cases, during the application of the stimulus, there actually was pain?—Well, I believe that there really was no pain.

3408. But supposing the extreme case which I now understand you to doubt, supposing that during the application of the stimulus itself, there was pain so long as the stimulus lasted, that must be by no means taken to imply that the animal was suffering pain before that strong stimulus was applied?—Certainly not.

3409. So that it would be a very erroneous conclusion to draw from your statement that when the animal was pinched it showed signs of pain, that therefore the animal was conscious of pain during the whole experiment?—Certainly it would.

3410. In fact the case is very parallel to that of a man who is in a dead slumber, whom you may rub gently in various parts of his body without disturbing him, but if you pinched that man, he would show pain, and feel it?—Yes.

3411. But it would be a strange conclusion to draw from that that he was suffering the whole time that he was asleep?—Yes.

3412. The two cases are parallel in your view?—Quite.

3413. With respect to the barking mentioned in one of your experiments, I would ask you whether the description which I am about to give of a very well known experiment is not correct: a frog is deprived of its cerebral hemispheres so as to be absolutely in the position of a machine incapable of suffering pain; and if under those circumstances, after the operation is recovered from, and the frog is perfectly well again, you take it up, and gently stroke it along the middle of the back, the frog gives a violent croak?—Yes; I know the experiment perfectly.

3414. Now that croak is exactly analogous to a dog's bark, is it not?—Yes, quite of the same nature.

3415. And you may treat that frog as you would a repeater; every time you stroke it on the back it croaks, and then it sinks back again into a state of absolute insensibility?—Yes.

3416. But inasmuch as that is not the least evidence of pain in the frog, it is quite clear that the corresponding action of the dog, which is a bark, cannot be taken in itself to be an evidence of pain?—Just so.

3417. A dog unconscious may bark just in the same way as a frog may croak?—Yes.

3418. So that you may have really very strong experimental evidence to ground your conclusion on that under the circumstances which you indicate, the dog did not really feel?—Yes, that the dog was quite insensible to any pain.

3419. So, again, even to take the most singularly combined actions, those actions which appear to show consciousness in the highest degree, inasmuch as they show rational adaptation of means to ends, I daresay you are familiar with the phenomena of mesmerism?—Yes, I have seen them.

3420. You may have possibly seen cases where a person being tested by yourself was absolutely insensible to physical pain?—Yes.

3421. Yet that person will answer a question rationally, and will do various and sundry complicated actions?—Yes, and surgical operations may be performed under that state without the individual suffering the slightest pain. It has been employed as a means for producing anæsthesia for surgical operations.

3422. I apprehend that you would say that the condition of the brain of a person in the mesmeric state doing these things, you have every reason to believe is of an analogous kind to the condition of the brain of the dog upon which you are performing your operation?—Yes.

3423. And as you are quite clear in the one case that there is no sensibility to pain, so you have reason to believe with moral certainty that it is so in the other case?—Yes.

3424. Then I observed that you answered with very great caution the question whether you would interfere with persons who were performing experiments which appeared to be unimportant, or trifling. I presume that one ground for your caution in answering was your knowledge, common to all of us who have followed the progress of science at all, that the observation of facts, and seemingly facts of the most insignificant character, has, in many cases, resulted in discoveries of the very greatest importance. I would merely mention, as an example, the very well known case of Galvani's observation of the frog's legs, which twitched when, under certain conditions, they were touched by different metals. Now, it is the case, is it not, that a very large proportion of our knowledge of the nerves and the physiology of the nervous system, has grown absolutely out of that observation, insignificant and trifling as it may seem? —Yes, the whole theory of animal electricity being founded on it.

3425. So that, with such facts as are before you, you would not unnaturally feel a very great hesitation in interfering with research, because to a man's contemporaries it may appear trifling?—Yes; I should say there would be great danger in subjecting any inquirer to the inspection of another person who was not able to enter into all the conditions of the problem which he had set before him.

3426. But I understand that, at the same time, you would view with the greatest moral abhorrence any man who should undertake a series of painful experiments, without being perfectly convinced in his own mind, whether rightly or wrongly, that they would bring forth good results?—I should.

Mr. D. Ferrier, M.D.

27 Oct. 1875.

3427. (*Mr. Erichsen.*) With regard to consciousness under anæsthetics, have you observed in surgical operations that a patient will wake up from the anæsthetic and be perfectly conscious, and ask whether the operation has been done, and be incredulous that it has been performed, and remain in that condition of perfect consciousness for some minutes without feeling the slightest pain from the operation which has been performed ?—Frequently I have seen that.

3428. That is a common matter, of every day observation ?—It is.

3429. And it is a common matter also, in those cases in which a surgeon wishes to keep up chloroform for a period of 10 or 12 hours, say in the compression of an artery for aneurism, that the patient is allowed to recover, and the chloroform is only given intermittently, at lengthened periods, periods of 10 minutes or a quarter of an hour; that it is interrupted and given again ?—Yes; but sufficient completely to lull sensibility.

3430. Although the person is more or less conscious throughout ?—Yes, apparently conscious, but absolutely unconscious to pain.

3431. (*Chairman.*) Is it sometimes the case that a patient who has been under chloroform can describe what has been happening during the period of the operation, and yet will say that he has not suffered any pain ?—I have heard of such cases ; I think they are rare, but still I have heard of them.

3432. Is there anything further that you wish to say ?—No, I think not.

The witness withdrew.

G. Hoggan, M.B.

GEORGE HOGGAN, M.B., called in and examined.

3433. (*Chairman.*) I believe you were formerly in Her Majesty's Indian Navy ?—Yes.

3434. Have you paid particular attention to the subject which has been referred to us ?—Yes, I have paid particular attention to it. I have studied and acted as an assistant in a laboratory.

3435. I think you have taken a great interest in the subject from a desire to diminish the sufferings of animals ?—From a desire to diminish the sufferings of animals, purely.

3436. Now do you advocate the total abolition of the practice of trying experiments upon living animals ?—No, I am not prepared at present to advocate the total abolition of vivisection.

3437. Do you think then that it ought to be permitted under certain conditions ?—I do.

3438. Have you considered what those conditions ought to be ?—I have.

3439. Will you be so good as to state the result of your consideration ?—The conditions which I should like to see if it continued would be those in which all that was done might be made amenable to public opinion, so that all that was good in vivisection might be utilised, and all the abuses connected with it might be put a stop to.

3440. Have you considered in detail how those objects might be attained ?—I have ; I have considered it and discussed it with other men, and the result of what I thought would be best, and what many others who belong to the same party that I do, that is, not wishing to have total abolition but restriction, agreed with me in, I am prepared to state.

3441. Will you have the goodness to state to us in detail what you would recommend should be done ? —If vivisection is to be permitted under conditions for the prevention of abuses in connexion with it, it ought only to be allowed under circumstances where public opinion might be brought to bear upon it. With this intention the following suggestions are offered. First, all secret or private physiological experiments involving the infliction of pain or wounds upon animals to be absolutely forbidden by law under heavy penalties, involving imprisonment. Secondly, all physiological experiments necessitating wounding or infliction of pain upon animals to be conducted in a suitable hall fitted with the necessary tables and apparatus for practising vivisection. The area of the hall thus provided to be overlooked by a gallery, or galleries, into which the public could have unrestrained access by separate doors. This would offer the following advantages. (*a.*) All experimenters claiming to be humane in their practice of vivisection would thus enable the public to form a correct estimate of their pretensions. (*b.*) As the public would not be admitted into the area, there could be no inconvenience to experimenters from crowding round tables or acts of mistaken zeal or feeling. (*c.*) The public mind and conscience accused at present of exaggerations would thus be afforded an opportunity of calming and rectifying itself, if no cruelty or other abuses were to be witnessed. (*d.*) Any abuse or act of cruelty might be witnessed by the public and the guilty party prosecuted and punished at their instance. (*e.*) The animals on which experiments were being tried would be protected from cruelty by the presence of the public. (*f.*) Experimenters would be forced to be on their guard against allowing any cruelty or even the appearance of it. They would thus be rendered more thoughtful of the sentient being under experiment, and would therefore resort to vivisection only when such seemed necessary or advisable for the elucidation or proof of some important fact. (*g.*) Any person might have the power of experimenting there, without special license or qualification, under the charge of the superintendent of the institution, who, except on the proof of a conviction for cruelty, could refuse admission to none while any table or place remained vacant or unused. (*h.*) Any student of medicine wishing to make a speciality of physiology could acquire a useful knowledge of this science from the gallery, whence he could watch every step in the operation of preparing for and performing the experiment. This is an advantage which cannot be obtained in the best organised classes in the world, and is of primary importance. (*i.*) Any of the students seen in the gallery might be asked to assis. in the area at any experiment by any of the operators The number of such assistants to be limited (say to five), so as not to inconvenience neghbouring experimenters, or permit the place to be converted into a class room for witnessing demonstrations upon animals. This measure would benefit the three parties, as an extra assistant might enable the anæsthesia to be kept perfect, while by closer observance the student would learn better, and the operator would have his hands set free for his more special part. (*j.*) For a like reason, the number of persons in the gallery ought also to be limited, say to 10, of whom only five might be medical students ; all admission therein to be by tickets issued gratis by the superintendent to all respectable persons above the age of 18 who might apply for them, something like a reading ticket for the British Museum. (*k.*) For the benefit of the students, or the information of the visitor, a placard containing notes of the case to be hung in the gallery opposite the experiment to which it refers. The anæsthetic, the course of operation, and the design aimed at, to be fully stated therein by the operator. This card to be held as the card giving admission to the operator into the area, and to be retained and filed afterwards by the superintendent ; like the card case hung over a patient's bed in some hospitals. (*l.*) It has been objected that no discoveries in science could be prosecuted in such a place, as they would become known before the discoverer published them, and thus he would lose the coveted fame ; and that consequently such discoverers would be discouraged from using the institution. This is possibly the best argument that could

G. Hoggan, M.B.

27 Oct. 1875.

be offered in favour of such a plan, as, while habitual or dilletante vivisectors would be discouraged, all earnest workers for the good of humanity would not hesitate to work openly in it at any experiment necessary to establish some important or beneficial truth. (*m.*) Animals on which it is intended to study the course of disease shall after innoculation, or operation in the hall, be retained in premises connected with and attached to the institution. These shall also be freely accessible to the public. No animal suffering from very painful wounds to be allowed to live, and if in the course of any induced disease the animal appears to suffer greatly, it shall be destroyed at once; and any neglect to do so shall constitute an act of cruelty for which the owner primarily,—failing whom the superintendent,—shall be held responsible. (*n.*) Any person or corporate body to be at liberty to form or build such an establishment, for which, after it has been inspected by an officer of Government, a license or permit gratis, or at a nominal fee, shall be issued, giving power to keep open the same under charge of a superintendent, who shall be held responsible for any irregularity or cruelty which may occur, along with but after the person committing the offence. He shall grant by the afore-mentioned card, admittance to use the area to any respectable person, and retain the same afterwards as a record of the operation. Admission to be granted on payment of certain stipulated fees for hourly, daily, or weekly use of the place. (*o.*) In this establishment all wounding of animals calculated to cause much pain under normal conditions to be effected only while the animal is fully under the influence of some anæsthetic or narcotic, and thereby rendered insensible to pain.

You will observe that this does not include the whole of an experiment, but only that portion in which pain is being inflicted by some preliminary operation.

(*p.*) Curari, or its supposed physiological analogues, is never to be used during wounding of, or upon wounded animals during any experiment. (*q.*) Lastly. Experiments should be strictly limited to the less sensitive and intelligent animals and it should be prohibited to vivisect horses, monkeys, dogs, and cats.

These are the general conditions that I have to propose. You will see that they aim principally at making vivisection as easy as possible when it is conducted in a proper way. While it prevents all secret vivisecting, it lays the path open and free for anyone to pursue vivisection under those proper restrictions. I recommend no special alteration in the law regarding Cruelty to Animals. That law could be applied there in each special case. In fact, it often would be very hard to say when an experiment was justifiable and when it was not. The circumstances of each special case would probably be the best guide upon which to rely. No hindrance is by this proposal placed in the way, in regard to license, or profession, or age above a certain point, but everything is done in order to render public experiments, with public opinion to bear upon them, as easy as possible.

3442. You mentioned having communicated on the subject with several other persons. Are we to take that which you have just put before us as representing your own individual opinion only, or as representing any society or body of persons?—It represents no society, but it represents the opinion of many who kept up this agitation for restriction before ever any society was instituted by writing and otherwise.

3443. Are you authorised to mention any names?—I am not authorised to do so; I have not asked the question. I have no doubt the parties would be quite willing.

3444. We are to consider you then as representing your individual opinion upon the subject?—You may.

3445. (*Lord Winmarleigh.*) Are the parties that you represent here, at whose suggestion you have come here, unanimous in the recommendation of those regulations, or have they been discussed by them?—They have been discussed by them.

3446. And are they the result of any resolutions passed by them?—They were first drafted out, read to different parties, their opinions got upon them, and alterations made where they wished it, until we seemed all agreed upon the point.

3447. And were those resolutions passed with the express view of your coming here to represent them?—Yes.

3448. Is that long since?—No, very lately.

3449. Since the appointment of this Commission?—Since the appointment of this Commission.

3450. May I ask if it is a large number of persons?—No, I have not made it an official communication.

3451. (*Chairman.*) Are you prepared to put in a list of any considerable number of persons who would adhere to this suggestion of yours?—I am.

3452. Will you have the goodness to do so?—I shall endeavour to do my best for that purpose.

3453. (*Mr. Forster.*) You said that you had been an assistant when experiments were performed as I understood you?—Yes.

3454. Will you describe to us what kind of experiments they were?—Yes, and I am prepared under a separate heading to state what I consider some of the abuses in vivisection; and I am prepared to illustrate by experiments which I myself have witnessed and assisted at. First, I consider one of the abuses of vivisection to be the repetition of fundamental experiments already classic, by experts, by way of showing their skill or showing an interesting point to a visitor in the laboratory, as the case may be. As an example of that sort I choose the action of the various nerves upon the secretion and the circulation of the sub-maxillary glands. The operation was first, at all events, best described by a professor whose name I do not know that I am liberty to mention.

3455. Is that experiment to which you allude an experiment mentioned in the 240th page of the first volume of a journal of physiology published under the direction of Dr. Brown-Séquard?—Yes, it is an experiment mentioned in that and the next page.

3456. (*Chairman.*) Have you witnessed the exhibition of this experiment yourself?—I have.

3457. Is it one which involves great suffering to the animal which is the subject of it?—It involves great suffering,, and it is impossible almost to give any narcotic in that case, because it would interfere with the course of the experiment.

3458. Now, have you seen this experiment performed in this country?—I have not.

3459. Do you know at all whether the practice in regard to experiments in this country is accompanied with the same pain to animals as elsewhere?—Certainly, there can be no difference. Vivisection is the same all the world over.

3460. Have you seen vivisection in this country?—I have seen a little; I have done some myself.

3461. Does it consist with your knowledge whether the experiments performed in this country are so severe as you say you have seen them on the Continent, and of which you have just given us an instance?—The course of the experiment must be exactly the same. Every step as it is described by a foreign experimentor must be followed step by step in any repetition of that experiment here; there must be no addition of narcotic or anæsthetic where such is not pointed out, or else the result will not be the same. The experiments are necessarily the same wherever they are performed.

3462. Would you have the kindness to tell me where you have seen experiments in this country?—I have done them myself. I have seen animals experimented on with strychnine in this country. What I have seen in a class has been very little. The thing is altered now, as I know from documentary evidence which I have here, from what it was at the physiological class of the University of Edinburgh five or six years ago. The only thing I saw there was on a frog. There is evidence from the professor himself to show that it is very different now.

3463. Can you put in evidence to show that severe

G. Hoggan, M.B.

27 Oct. 1875.

experiments are performed in Edinburgh in a class, and without anæsthetics ?—No, I cannot say that; but I know that experiments are performed in Edinburgh without anæsthetics, and I have documentary evidence for that.

3464. Will you be so good as to produce it ?—This which I hold in my hand is an account which came into my hand only on Saturday from the British Medical Journal. My mere opinion upon these experiments is that they were very cruel, very painful, and as far as I can see they were useless, and not to be depended upon as far as application to man was concerned. Animals, namely dogs, were kept fasting, in the first place, for 18 or 19 hours, a thing that would never be attempted upon the human being upon which cholagogues were being administered. Curari was given, a substance the effect of which on the liver has not yet been examined thoroughly, but we know this, that in almost all glands it increases the secretion very much, and would throw matters into an abnormal condition. The animal has been kept under curari when there was no anæsthetic, no narcotic given; no narcotic, indeed, could be given, for there it would interfere, as a separate drug, with the experiment. Therefore, those animals, from the time that they were placed under curari, were kept under curari eight, seven, six, and five hours, suffering pain in consequence of an operation being performed which opened their abdomen, an operation made to find out the bile duct, and separate it from the other structures which lie with it in the gastro-hepatic omentum. A glass cannula is then tied in the bile duct, and the bile drops by means of a tube. All that human beings know is the pain there is when gall stones are passing down the bile duct, and that is known to give excessive torture. Merely a little bit of fat passing down gives us intense pain, and we can form an opinion that to take out the duct, to disturb all these parts, and manipulate it, as has been done, would cause more intense pain. And in that condition the animals were kept conscious and fully sensitive (I have any amount of evidence to prove this if there is any doubt about it), while the experiments were being tried upon them. I say that the conditions were abnormal to such a degree that they could never be applied to men; and that the pain was excessive; and that the experiments were uncalled for, and cruel in the extreme; and I put in a paper by Dr. Rutherford himself, in the British Medical Journal of October 23rd, as evidence of that point. This view of Dr. Rutherford's only forms another of the numerous opposing views on the same question; agreeing on one point only with the committee who sat in the same university, and the professor who was in the same chair before him a few years ago, (and under whom I received my tuition,) namely, that mercury had no effect on dogs. Nearly the whole medical profession agree that it has a great effect on human beings. So that the only point on which these people agree, after all their cruel experiments, is, that what is applicable to the dog is *not* applicable to man.

3465. (*Mr. Forster.*) I propose now to ask you with regard to the experiments in England that you have actually seen. Would you kindly tell me the experiment implying the greatest amount of suffering to any animal that you can recollect that you have ever seen in England ?—The only experiments that I can speak to in England (seeing that I went to France to acquire a full knowledge of vivisection, and that when I had seen it, I did not care about coming over here to practice it), were little things that as a student I did myself, and have seen others do. I have seen experiments for instance connected with strychnine.

3466. Will you kindly describe the sort of experiment ?—Simply this; a person thought he had discovered a cure for strychnine. It was a silly thing altogether, but he invited me to witness it. He had already experimented on a large number of dogs.

3467. Was this in a laboratory ?—No, it was not in a laboratory, it was in a private cellar, and not by a medical man; but he supposed that he had a knowledge of medicine, he had attended some of the classes. The strychnine was given, and the cure was to be to use the galvanic battery upon it. It was simply useless, the animal suffered greatly from convulsions caused by strychnine, and died as one would expect, and as many others had done before it.

3468. Upon how many animals was that experiment tried in your presence ?—It was tried on one in my presence, and another was lying dead.

3469. And how long would that animal be under the influence of strychnine before death ?—I did not exactly watch the time, but I suppose about a quarter of an hour or 20 minutes. The dose I may say was not very strong in order to give the antidote a chance of working, and therefore lengthened out the experiment.

3470. Can you give me any other case that you have witnessed ?—None except my own.

3471. Do you object to telling us what you have done yourself ?—No. I would simply say this, that I never got further than administering the anæsthetic. I have done that with three or four animals, and they died under my hands. I wished to save them all pain. I was strongly urged to try experiments by my teacher, and by others, on a subject that had already been published; I refused to do so, and tried quite by myself whether I could administer the anæsthetic and go through it. I found I could not do it, and therefore I refused to go further into the question until I had learned how vivisection was done.

3472. Am I to understand that you were advised by the lecturer, whose lectures you attended, to try experiments yourself ?—I was advised by nearly everyone of my own friends to do so, and the lecturer, my own teacher, offered to associate himself with me, and put his own rooms at my disposal for the purpose.

3473. (*Lord Winmarleigh.*) Was that in England or abroad ?—In Scotland.

3474. (*Mr. Forster.*) It was when you were studying medicine in Scotland ?—When I was studying medicine in Scotland. I was demonstrator of anatomy at the time.

3475. At what place ?—At Edinburgh.

3476. Were you recommended to try these experiments not merely as a student of medicine, but as being in the position of a demonstrator of anatomy ?—I was a student of medicine while I was demonstrator of anatomy; and this theory which I had devised, and which was hotly debated in Edinburgh for some time, was a new mechanical theory of respiration, upon which I wrote a dissertation, which was read before the Royal Medical Society there. That was a part of it.

3477. Then I would ask you this question, Was the advice that was given to you to try experiments advice that was given to you merely as a student of medicine like other students, or was it advice that was given to you in order that you should investigate the particular theory that you were advancing ?—It might have been either, it might have been both; that is to say, whether I was a practitioner or a student, if I devised a question that required proof, I should have been equally advised in either case to try experiments.

3478. Do you think that, judging from your own experience at Edinburgh, the lecturers generally advise the students to try experiments for themselves, independently of the experiments that were tried in the lecture room or in the laboratory ?—I certainly can speak for myself, and say that I was advised by many; by several of my teachers, by many medical men, also by all the students about me, who all said, "You "have laid it out beautifully in theory, but you "must show by experiments how it is done; you "must try experiments on animals, and publish your "theory along with those experiments."

3479. Do you think that a similar advice was given to other students ?—I have no doubt of it whatever, because several students have told me; one told me, who is now dead, that he had performed 10 or 15 experiments on cats shortly before then, and recommended me strongly, as what he had seen was so very clear, to get cats and dogs and examine the action of the various muscles in those animals that I had contended in my dissertation had not the use that was assigned to them.

3480. When this advice was given to you to try experiments, was it accompanied with any advice to subject the animals to as much anæsthesia as possible?—There was no question of anæsthesia at all.

3481. Do you imagine that in consequence of this kind of advice there was much private experimenting by the students?—I do.

3482. I think I must ask you what was the name of the professor who advised you to try these experiments?—Dr. Handyside, lecturer on anatomy.

3483. Is he a lecturer now?—Yes, and he offered to associate himself with me in the whole theory, and place his rooms at my disposal in order to elucidate the theory, or rather to illustrate it, by means of experiments.

3484. Then you give this as a fact that you desire us to take upon your own personal knowledge, that at the time that you were studying medicine at Edinburgh, it was common for the medical students to try private experiments, and that with the knowledge and concurrence and approval of the lecturer?—I do.

3485. What year was that?—About 1871–2, I think.

3486. Do you imagine that these private experiments were generally performed with anæsthetics when that could have been done without marring the success of the experiments?—No. My reason for thinking so was the fact of one gentleman now in practise advising me not to have cats, because they made such a squalling and scratching when you began to cut them.

3487. Was it a man senior to yourself?—He was senior to myself.

3488. Had he any official position in the university?—He was demonstrator of anatomy before me.

3489. I think I must ask you his name also?—Dr. Alexander Sinclair, now in practise in Edinburgh.

3490. (*Mr. Huxley.*) At the time that you speak of, when you were a student advised to perform these experiments, how long had you been a student?—I got advice continually from the time when I had been about only a year and a half a student up till the time that I finished there.

3491. I wish to refer particularly to the advice given to you by the responsible person whose name you have mentioned. You have stated that Dr. Handyside advised you to perform certain experiments. At what time in your career was that, how long had you been a student when he gave you that advice?—I may say three years. The advice was often given, but I give that as one term.

3492. I am now asking about this particular case, and will not trouble you to tell me anything about the others. Am I right in supposing that at the time that Dr. Handyside gave you this advice you had been a medical student for three years?—Yes.

3493. You were, I presume, then looking forward before long to take your degree?—Well, I cannot give a direct answer to that.

3494. Did you take your degree?—I did take my degree.

3495. In what year did you take it?—I took it in 1872.

3496. How long was that after you commenced your medical studies?—I commenced my medical studies in the session of 1868–9. You have asked if I was looking forward to taking any degree. All the time of my student life I had no specific looking forward of the kind. I merely went to medicine by way of filling up my time. I had retired from the service, and made medicine a sort of a pastime; so you will understand now why I was not looking forward to my degree. I did not care much whether I got it or not.

3497. May I take it then that you commenced your medical studies in 1868–9, and, as a matter of fact, did take your degree in 1872?—I did.

G. Hoggan, M.B.

27 Oct. 1875.

3498. Then, I presume, that this advice given by Dr. Handyside was given to you shortly before the time of your taking your degree?—About a year before.

3499. Under these circumstances, you had passed through, I presume, at least two winters' instruction in anatomy. Is that not so?—Two winters' instruction in anatomy.

3500. You had also passed through two sessions, or, at any rate, one session of instruction in physiology?—One.

3501. You had also passed through your chemical courses?—Yes; one.

3502. And, I may say, that you had received all the preliminary instruction in medical science which it is customary to give in the university, that is to say, all that instruction upon abstract science as apart from medicine and surgery which is usual?—I had had no instruction in practical physiology.

3503. But you had received all the instruction that you were likely to get in anatomy and physiology, all that it was necessary for you to have in order to obtain your degree?—Yes.

3504. So that when this case is brought before us as an illustration of a student being urged to perform vivisections, when we come to look into the matter, the real fact is that that so-called student had at that time received all the instruction in anatomy and physiology that the university had to give him?—That is relating to this one occasion; but I told you there were several of the same kind from the same teachers.

3505. If you will allow me, I will take this specific case, because it affects the reputation of a gentleman in the university who has been named, and until that case has been disposed of it may be convenient not to deal with anything else. At the time this advice was given to you, so far from being a raw or inexperienced person, you had received all the instruction in anatomy and physiology that you were likely to get, and you had all the skill in anatomy and physiology that you were likely to possess. That is so, is it not?—On this one occasion I ought probably to correct that answer; I did not know whether that was all that I was likely to get, because I felt that I was incompetent at the time; and it was because I was incompetent that I refused to do it.

3506. You refused to do it because you felt that you were incompetent?—I did.

3507. May I ask you if it is not very much the custom at the University of Edinburgh for a student who takes his degree to present on the occasion of his taking his degree what is called a thesis?—The custom is the opposite; that is to say, it is not so much the custom as it is not the custom.

3508. Let me ask, does it frequently happen that students who are going to take their degree in the University of Edinburgh, present these on the occasion?—No, it does not.

3509. It does not frequently happen do you say?—It does not frequently happen I believe. A student leaves the university as a student for two years at least before he has to present a thesis, and it is supposed that during that time, after he has left as a student and taken his degree as a Bachelor of Medicine, he will employ himself in preparing a thesis for M.D.

3510. The degree of medicine to which I was referring was the Doctor of Medicine. I will put my question again more distinctly. It is commonly the case, is it not, that a student, before taking his degree as a Doctor of Medicine, presents a thesis?—The student of medicine does not take a degree of Doctor of Medicine now in the University of Edinburgh unless he began 10 or 12 years ago. The student of medicine in the University of Edinburgh first gets his M.B. degree, and remains outside the university, or at all events in practice for another two years before he can present himself with a thesis for M.D.

G. Hoggan, M.B.

27 Oct. 1875.

3511. I think that this difficulty turns upon the technical sense of the word "student." Does a person who has taken his Bachelor of Medicine degree, and intends to proceed to be a Doctor of Medicine, in any proper sense of the word in any but a technical sense, cease to be a student?—He ceases to be a student in a technical sense; he ceases to be a student when he gets his M.B. degree.

3512. Then what you referred to just now was that he was not technically a student?—That he was not technically a student.

3513. In order to make my question accurate, will you allow me to ask whether it is not the custom and a frequent practice for a person proceeding for examination for his degree of Doctor of Medicine to present what is called a thesis?—No gentleman goes to examination for an M.D., there is no examination for M.D., all your medical examination is closed at M.B.; anything medical after that is confined to the presentation of a thesis, and it is for that purpose that you are supposed to remain two or three years after obtaining your M.B. degree.

3514. I am quite content with that. Let me put my question in another shape. Is it not usual or common before a person obtains his Doctor of Medicine degree for him to present a thesis?—Yes; it is imperative.

3515. Now, among the best students it is not uncommon for them, when they attain the condition of persons seeking to obtain a medical degree, to take for the subject of their thesis something requiring original research; that is so, is it not?—It is, unfortunately, true.

3516. But whether fortunate or unfortunate, it has for many years been the practice of the university, and it is considered a certain distinction, whether rightly or wrongly, on the part of the person proceeding for his medical degree, to present a thesis containing the results of some original research, that is so, is it not?—It is a custom for them to make researches; but I am not prepared to say that it is considered as an additional qualification that they should do so.

3517. I did not say an additional qualification; I said a distinction to have done so?—It is something to have done it; I would not say a distinction.

3518. I did not ask your opinion as to whether it was a distinction or not, but whether the authorities of the university considered it a distinction or not; whether, for example, they do not award gold medals for some of those theses; that is, within your knowledge?—Yes, it is within my knowledge that they award gold medals.

3519. Now, whether they do rightly or wrongly, I will ask you, is it not within your knowledge that the professors and teachers in the University of Edinburgh think it their duty to encourage any young man who shows a certain amount of scientific aptitude to carry out original research, and to embody that original scientific research in the thesis which he presents?—You put a question to me that I think ought to be put to the authorities of the University of Edinburgh. I cannot speak for those authorities.

3520. I ask you whether you know as a matter of common notoriety, having been in the University of Edinburgh yourself, and knowing a great deal about its affairs, that that is the case or not?—I do not pass any opinion upon that.

3521. You do not know it?—I do not pass an opinion upon it.

3522. You say that you know nothing one way or the other?—Simply that I have not been advised by any of the authorities to put in a thesis to the University of Edinburgh.

3523. And you do not know that that is the practice in the University of Edinburgh?—I know that the question of putting in a thesis is often spoken about with a sneer. I can only say that much; I could not speak for the authorities themselves.

3524. I then understand you to say that you do not know that the professors and teachers in the University of Edinburgh encourage young men to do this?—I have no special personal knowledge on that point.

3525. You are not aware that a professor in the university would think that he had failed in his duty if he did not encourage a young man who showed aptitude for original research to follow it?—I have not so very high an opinion of all the authorities in the university.

3526. I did not ask your opinion about the authorities in the university; I asked whether it was in your knowledge or not that they do a certain thing. You have been in the university, you have lived in Edinburgh, you have been a teacher in a school, which occupies itself in preparing persons for examination, and I ask you this simple question, whether you, having those opportunities of being conversant with the practice of the university, do or do not know that it is the habit of the professors of the university to encourage young men who show aptitude for original research?—No, I do not know it; I have never experienced it.

3527. You have never yourself you say been the subject of such a recommendation?—No; it is a question of favouritism in general that brings on young men in the university.

The witness withdrew.

Adjourned to to-morrow at 2 o'clock.

Thursday, 28th October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.

JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

Mr. E. Klein, M.D.

28 Oct. 1875.

Mr. EMANUEL KLEIN, M.D., called in and examined.

With respect to this evidence see Report, p. 1, and Appendix, Part II. § 2.

3528. (*Chairman.*) Are you Assistant Professor at the Laboratory of the Brown Institution?—Yes.

3529. Do you hold any other public appointment?—I am Lecturer on Histology at the Medical School of St. Bartholomew's Hospital.

3530. Are you the author of the first section of this book, which is known as a handbook for the physiological laboratory?—Yes.

3531. Now are any of the experiments which you describe in that book experiments of a painful character?—Many of them are.

3532. Necessarily so?—Necessarily so.

3533. What was the intention in your view of the book as regards the practice of those experiments; are there any limitations to that practice?—It is a

Mr. E. Klein, M.D.

28 Oct. 1875.

guide for students working in a laboratory under the supervision of some person who understands and has to direct them how to do it; that they should not do it anyhow, but according to certain principles accepted in every laboratory.

3534. You have drawn in that book, I think, no distinction as to where anæsthetics are to be used, and where they are not?—No.

3535. Is that purposely on your part?—It is understood that the experiments mentioned there are done under anæsthetics, except where it is expressly mentioned that they are not so.

3536. But there is no general indication in that book; I think that such is the case?—No, I do not think there is.

3537. Do you think there ought to have been?—Well, as I said before, it is to be a guide in a laboratory, not for private persons or amateurs; and there exist in every laboratory certain rules from which no one is allowed to deviate.

3538. What is your own practice with regard to the use of anæsthetics in experiments that are otherwise painful?—Except for teaching purposes, for demonstration, I never use anæsthetics, where it is not necessary for convenience. If I demonstrate, I use anæsthetics. If I do experiments for my inquiries in pathological research, except for convenience sake, as for instance on dogs and cats, I do not use them. On frogs and the lower animals I never use them.

3539. When you say that you only use them for convenience sake, do you mean that you have no regard at all to the sufferings of the animals?—No regard at all.

3540. You are prepared to establish that as a principle which you approve?—I think that with regard to an experimenter, a man who conducts special research, and performs an experiment, he has no time, so to speak, for thinking what will the animal feel or suffer. His only purpose is to perform the experiment, to learn as much from it as possible, and to do it as quickly as possible.

3541. Then for your own purposes you disregard entirely the question of the suffering of the animal in performing a painful experiment?—I do.

3542. Why do you regard it then when it is for a demonstration?—Because I know that there is a great deal of feeling against it in this country, and when it is not necessary, one should not perhaps act against the opinion or the belief of certain individuals of the auditorium. One must take regard of the feelings and opinions of those people before whom one does the experiment.

3543. Then am I wrong in attributing to you that you separate yourself entirely from the feeling which you observe to prevail in this country in regard to humanity to animals?—I separate myself as an investigator from myself as a teacher.

3544. But in regard to your proceedings as an investigator, you are prepared to acknowledge that you hold as entirely indifferent the sufferings of the animal which is subjected to your investigation?—Yes.

3545. (*Lord Winmarleigh.*) Had you practised before coming to England?—Yes, in Vienna.

3546. Do you believe that that is a general practice on the Continent, to disregard altogether the feelings of the animals?—I believe so.

3547. Have you, since you have come to this country, had any proof of what you state now with regard to the different feeling that pervades the inhabitants of England with regard to the feelings of the animals on which you operate? Have you had any instances of the contrary feeling to that which you have just mentioned, on the part of Englishmen, since you have come to this country?—Yes, there is a great deal of difference.

3548. You have seen it exhibited?—Yes.

3549. Would you give the Commission an instance in which any such feeling has been exhibited?—I mean with regard to the journals; the outcry and agitation carried on in the different journals against the practice of vivisection. There is no such thing abroad; there the general public takes no view, does not claim to pronounce any criticism or any judgment about scientific teaching or physiology in general.

3550. But with regard to the pupils before whom you lecture, have you ever seen any indication on their part of a disinclination to inflict unnecessary pain on animals?—If I do perform a painful experiment where chloroform cannot be used, because it is against the purpose of the experiment, then I ask those before whom I do the experiment, whether they object to it.

3551. And what have you found?—If some of them do object then I do not do it before them.

3552. Have they objected?—Very seldom. With the exception of one or two it has never happened that they have objected.

3553. But you believe that generally speaking there is a very different feeling in England?—Not amongst the physiologists; I do not think there is.

3554. But amongst the people of England do you think there is a very different feeling from what exists upon the Continent on this subject?—Yes, I think so.

3555. Seeing that there is that feeling, have you found that in yielding to that feeling in your lectures your experiments have not been so effective as they would have been if you had acted without anæsthetics?—Well, really I could not say.

3556. How long have you practised in England?—Four years and a half now.

3557. Always in London?—Always in London.

3558. You have never given lectures in the country?—No. I never do experiments in my lectures; I only do experiments for teaching purposes in my private class.

3559. To demonstrate?—To demonstrate.

3560. Could you tell the Commission any particular experiment in which you think it is absolutely necessary to act in demonstration without anæsthetics?—Supposing, for instance, one intends to bleed a young dog to death by opening a vessel. With young dogs it is almost impossible to produce narcosis quickly, it takes always a considerable time; it is much sooner done by an assistant fixing the dog; at one cut the carotid may be exposed, and the vessel may be opened in less than half a minute, whereas with chloroform it would take a much longer time; the animal would howl, and would, I have no doubt, suffer a great deal more than when it was done without anæsthetics.

3561. Would the dog howl and exhibit pain while under anæsthetics?—While being chloroformed it would.

3562. Could you explain more in detail why you think it necessary, besides the point of time, to abstain from the use of anæsthetics in cases of research?—I fancy the whole attention of the investigator is drawn to the purpose of the experiment. He has made clear to himself what he is going to do, how he is going to do it, and what he is going to learn by it. He generally chloroforms a dog when he experiments on a dog for convenience sake, in order not to be disturbed by the howling and the resistance; and so with cats. He does not do it with frogs. I do not think we have any right to regard the sensibility and feeling of a frog as being of a very high degree. And just as little as a sportsman or a cook goes inquiring into the detail of the whole business while the sportsman is hunting or the cook putting a lobster into boiling water, just as little as one may expect these persons to go inquiring into the detail of the feeling of the animal, just as little can the physiologist or the investigator be expected to devote time and thought to inquiring what this animal will feel while he is doing the experiment. His whole attention is only directed to the making the experiment, how to do it quickly, and to learn the most that he can from it.

3563. But do you think that where it is only a question of time a professor of physiology is not bound to consult humanitarian feelings?—I must again draw a distinction between an investigator and a professor

Mr. E. Klein, M.D.

28 Oct. 1875.

of physiology. I understand a professor of physiology is a man who teaches, and there I think it is quite right before a class that when one performs an experiment one should use anæsthetics, but an investigator has no time. I myself, when I am going to make an experiment for pathological research, have no time really with regard what the animal will feel.

3564. Is that really the only reason that you can give for not using anæsthetics?—It is to a great extent; it is the chief reason I should say; there is no place for considering that point.

3565. (*Mr. Forster.*) You mentioned, I think, that there were certain rules in laboratories; what are those rules?—That no one is allowed to make an experiment except a professor or the assistant professor is present and tells him to do it, and makes him acquainted with the purpose of the experiment, doing it perhaps the first time before the man who is going to repeat it.

3566. Do those rules in the English laboratories say anything about anæsthetics?—Well, generally it is understood, where it is not against the purpose of the experiment, that they are used; it is a thing understood by itself.

3567. Is that a written rule?—There is no written rule that I know of any kind.

3568. Have you found much progress in physiological science lately in this country?—I think so.

3569. You find more attention given to it than when you first came?—Yes, considerably more.

3570. And several students, I suppose, that attend your lectures take great interest in it?—Yes.

3571. Do you think that many of them are carrying on private investigations?—No; I do not believe that any private person carries on investigations except in a laboratory.

3572. Do they come to your laboratory and try experiments?—Yes; those who carry on private experiments in connexion with the Brown Institution all come to the laboratory, and do it under me or Dr. Sanderson.

3573. What is your connexion with the Brown Institution?—I have nothing to do with it, but I am only in the laboratory, which is part of the Brown Institution. My official position is with Mr. Simon.

3574. Your laboratory is in the rooms connected with the Brown Institution?—Yes, on the same ground.

3575. How do you get the animals that are practised upon in the Brown Institution?—We buy them.

3576. And do you buy them with funds that come out of the Brown Institution?—No; those used for pathological researches are not brought from the Brown Institution. These researches that I am conducting myself are for the medical officer of the Privy Council, and the expenses are defrayed by the medical officer.

3577. (*Chairman.*) By what medical officer?—Of the Privy Council, Mr. Simon; the expenses of the pathological experiments I refer to. The experiments have been very few in the last few years for special research, but those that have been made have been always in connexion with scientific investigation carried out for Mr. Simon.

3578. (*Mr. Forster.*) And have the animals upon which you have been experimenting in your researches and investigations been furnished by Mr. Simon?—I am speaking of those. Those for teaching purposes are bought quite privately.

3579. I want to know with regard to your own private investigations, are the animals that are obtained for that purpose, and upon which you try experiments, obtained with the assistance of Mr. Simon's grant out of the Privy Council?—I do not do any private experiments except for pathological researches for Mr. Simon.

3580. Have you done any other?—No.

3581. What are the experiments in pathological researches?—For instance, inducing artificial tuberculosis, or for instance, trying to communicate typhoid fever to the lower animals, or for instance, in the experiments on small-pox in sheep, or pyemia.

3582. You spoke about your own personal experience in what may be strictly called vivisection; that, I suppose, is not so much in this country as abroad?—To a great extent.

3583. Can you at all recollect what was the vivisectional experiment in this country with which you had to do which caused the greatest pain without anæsthetics?—I should think cauterising the cornea of a frog, for instance; it is mentioned at page 38 of the handbook.

3584. Would you be good enough to tell me the time that that experiment would last from the period at which you would first be obliged to give pain to the frog?—It greatly depends upon what kind of frog it is. If it is a large vigorous frog it takes a much shorter time than a small frog, for instance, a large frog from the Continent.

3585. This is not the frog which you get here, I suppose?—We get them from Holland.

3586. (*Chairman.*) You import them for the purpose?—Yes.

3587. (*Mr. Forster.*) Take one of those frogs, then, and tell me how long the experiment would last?—At present I do not practise it so long as the passage in the book would imply; I do not allow it stay an hour for the cauterisation. When doing it on living animals it takes say 10 or 20 minutes after cauterisation, the cauterisation itself takes little time.

3588. And what becomes of the frog after that time?—It is killed.

3589. (*Lord Winmarleigh.*) Always?—Generally killed; always killed.

3590. (*Mr. Forster.*) Have you performed any experiments in England upon dogs or cats; upon dogs, for instance?—Yes, I have.

3591. What sort of experiments?—I have injected pyemic fluids into the veins of dogs to make them pyemic, to produce pyemia, or septicæmia. So with cats. Then I have used dogs for producing tuberculosis, and I have used dogs and cats for producing typhoid fever.

3592. Have you cut up any dogs or cats by vivisection?—If I inject into the vein, I must cut; you cannot do it without cutting.

3593. Those are what you call pathological experiments?—Yes, for pathological purposes.

3594. I am now speaking of the other kind of experiments on living animals, which would be more strictly perhaps called vivisection; have you done them to dogs or cats in England?—No, not for the special purpose of demonstration.

3595. But have you for private investigation?—As I mentioned just now for experiments on pyemia, typhoid fever, septicæmia, and tuberculosis; not for others.

3596. Have you, for private investigation, tried any experiments on dogs or cats, not pathological, but physiological experiments?—No, not directly for physiological experiments. I may have used a dog which has been used at the same time for pathological purposes, also for physiological.

3597. (*Chairman.*) When you use a dog for physiological purposes, do you adopt any particular mode of fastening that dog?—No, it is fastened on a large board, the four limbs are fastened.

3598. And how are they fastened?—With broad bands.

3599. (*Mr. Forster.*) You were stating that you considered it was so important to be absorbed upon the object of the experiment, that you could think of nothing else, and therefore could not really, in your opinion, afford time to consider the feelings of the animal; do you not sometimes find an inconvenient interruption from the cries of the animal?—Only then I do use chloroform, that is what I said; I use anæsthetics for convenience sake.

3600. Do you ever use curari for that purpose, to stop the cries?—Curari involves other difficulties, the animal ceases to breathe because it paralyses the movement for breathing, and that might be against the object of the experiment. The animal, for instance, is to be kept alive after the experiment was over for some time; that could not be done after artificial respiration has been used.

3601. But practically, has not the howling of the dogs interfered with experiments?—Dogs do howl also when you chloroform them.

3602. Do you try experiments with any animals that do not signify pain so loudly?—Rabbits.

3603. They do not howl, I suppose?—They do not.

3604. Then of course the same motive would not induce you to use chloroform in their case?—No.

3605. In fact, I suppose with rabbits you would not use chloroform?—I use choral hydrate; but, as a general rule, for my scientific investigations, I do not use chloroform, or any other anæsthetic, except for convenience sake, in dogs and cats, and for no other animals as a general rule. There may be exceptions perhaps, but as a general rule, I think I am safe in saying I do not use it.

3606. You gave it as your opinion, that your views on the subject, although not shared by the British public generally, were the views of the British physiologists?—I would not say that distinctly, but I know a few of them, and I think that is the view held by them.

3607. What is your precise connexion with the Government department of the medical branch of the Privy Council?—In carrying out pathological investigations for Mr. Simon.

3608. That is to say, that Mr. Simon asks you to give him your assistance in a particular matter; there is no arrangement with you by which you may be considered an officer of the Privy Council, is there?—I do not think there is.

3609. (*Chairman.*) But the animals that are used for these purposes are paid for by the public money?—For my pathological inquiries only. I must mention that I make extremely few pathological inquiries. I have not made any other experiments of that nature, except those on artificial tuberculosis, on small-pox, and on typhoid fever. I understood that I was asked about my opinion, and I gave it, but it is another thing whether I actually do these things. If I were to be called upon to do experiments of these kinds, I would do them.

3610. (*Mr. Forster.*) I understand you to say, that as regards physiological experiments, you have not tried physiological experiments to any extent in England?—Very few.

3611. Have you done so at all in connexion with your employment by Mr. Simon?—No, none whatever.

3612. But what experiments you have tried have been tried in the Brown Institution at your own cost, I suppose?—In my private room. Those that I do for teaching purposes, physiological purposes, I do in my private room; I live there.

3613. Can you at all give us any idea of the number of animals that you find it necessary to obtain for experiments for medical investigations connected with the Privy Council?—At my work I do not think there have been more than 14 or 15 animals used in the whole of last year.

3614. (*Lord Winmarleigh.*) What were they?—There were three monkeys; of course, I would not call that vivisection; that is simply feeding them on peculiar stuffs, which has nothing to do with vivisection. I will leave out these therefore. Then there were three dogs and two cats, and a few mice, four white mice, I think.

3615. (*Chairman.*) Now in regard to the Brown Institution, what is your precise relation to the Brown Institution, do you receive any remuneration from it?—None whatsoever.

3616. You live in the building?—Yes.

3617. And this private room of which you speak is a private room belonging to the Brown Institution?—It belongs to the laboratory of the Brown Institution.

3618. That is to say, it is a part of the property held in trust by the London University?—I believe so.

3619. And you reside in it?—Yes.

3620. What is your particular duty to the London University?—I am ashamed to say I do not know; it has never been made clear to me what my position is there. A title has been given to me, that of assistant professor, and I am working in the laboratory, conducting pathological researches; those gentlemen who come there to undertake special researches work under my direction.

3621. And are these pathological researches for the benefit of the Brown Institution?—I do not know that it has ever been put down in that way.

3622. The pathological researches are made upon animals?—Yes.

3623. Are those animals furnished to you by the Brown Institution?—No; I make pathological experiments only for the medical officer of the Privy Council.

3624. Then for the London University you make no pathological experiments?—None.

3625. Then no animals are furnished to you by the London University?—None.

3626. Are these pupils of yours in any way connected with the London University?—No; they are pupils from different hospitals who wish to enter more closely into microscopical or histological anatomy.

3627. And in the teaching of those pupils you draw no distinction between painful experiments and non-painful experiments if the students themselves raise no objection to see the animal subjected to pain?—Yes; I think that would be quite what I expressed before.

3628. Therefore any students who come there, so far as your teaching and influence are concerned, adopt, I presume, the principle that you have adopted?—Yes.

3629. And consider that a physiological inquirer has too much to do to think about the sufferings of the animals?—Yes; may I be allowed to state, with regard to experiments for teaching purposes, that there are extremely few that I really do.

3630. But I presume that the experiments which you perform for original research are, many of them, of a painful nature?—I have performed very painful experiments with reference to artificial tuberculosis, because I regard it as very painful to produce a disease coming on very slowly in an animal by injecting into its abdominal cavity a foreign material; but I do not regard it as a painful experiment to inject typhoid fever into an animal, seeing that the material has no effect whatsoever.

3631. But now coming to vivisection proper, you do perform in this laboratory operations which involved a great deal of pain to the animal?—Yes, we do occasionally; of course they are very few.

3632. And without any question of employing anæsthetics, unless it happens to be for your own convenience to do so?—Yes.

3633. And that principle, so far as your influence goes, is derived from you by the pupils who come to benefit by your teaching?—That applies only to that part of the experiments which is for teaching purposes.

3634. (*Mr. Forster.*) With regard to the pathological experiments which you tried in connexion with Mr. Simon, you mentioned that there was one that is particularly painful, the one connected with tuberculosis?—Yes, tuberculosis and pyemia.

3635. And that is done by injecting?—Yes, by injecting a certain fluid into the abdominal cavity, or a vein.

3636. I suppose the operation of the injection is painful?—No, the injection itself is nothing, the consequences of the experiment are painful.

3637. Is there no operation which is painful?—I daresay injecting into the veins of a dog is a painful operation, the making a cut into the skin, but that is the whole thing.

Mr. E. Klein, M.D.

28 Oct. 1875.

3638. How long would that last?—Not half a minute.

3639. You give no chloroform, I suppose, when that is done?—No.

3640. Are there any other of these experiments which require what may be called operations in doing them?—No, except injecting into veins and injecting into the abdominal cavities. I would not regard that as a painful operation any more than injecting into a man. Besides those I do not remember any.

3641. When you take hold of an animal for this purpose, what is done with it; do you bind it up while you are making this injection?—If it is a large vigorous animal, as a dog, we do bind it and fasten it. A cat we generally must chloroform.

3642. Why do you not chloroform a dog?—We chloroform a cat because we are afraid of being scratched.

3643. Why not a dog?—If it is a small dog there is no fear of being bitten by the dog.

3644. I hardly need ask you, with your earnestness in investigation, you would run the risk of a scratch if you thought that giving chloroform would spoil the experiment?—Yes, if I had to open an artery to insert a cannula into it (I am talking only of conditions which may be; I do not say it has happened with me), I should chloroform it, not being scratched, and the cannula being torn out.

3645. Have you had any directions from Mr. Simon with regard to pathological investigations in consequence of any minute which I wrote when I was in the Privy Council?—Yes, I remember.

3646. Do you remember what they were?—Yes, I think I remember that it was your express desire to use animals for pathological experiments as little as possible, and to use poison producing as little pain as possible: those were the contents.

3647. Do you recollect anything definite in those instructions, or in Mr. Simon's instructions to you upon those instructions, with regard to the use of chloroform?—The fact is that I do not remember that we used any animal strictly for vivisection, except injecting into the veins and injecting into the abdominal cavities; for one could not call it vivisection injecting lymph of small-pox into the skin of a sheep, any more than one could injecting vaccine into the arm of a child.

3648. Have you ever had instructions from Mr. Simon, that with regard to experiments, pathological or physiological, conducted by you, chloroform was to be used in the case of any severely painful operation?—We had no severely painful operations.

3649. Would you inform him beforehand of what you were going to do in the way of vivisection?—No. I think Mr. Simon knows too much himself about scientific investigation to interfere with an investigator.

3650. I want to know whether he has ever told you, as a general rule, for your guidance, that in any severely painful operation chloroform is to be administered for any experiment connected with the Privy Council?—The only direction which Mr. Simon gives is, that he gives the thema to do this and that investigation; but to say how we are to do it, or to criticise the results we obtain, I do not think he ever undertakes.

3651. (*Lord Winmarleigh.*) He never gives directions under those circumstances, whether it should be done under anæsthetics or not; is that what you mean?—There is no occasion for him to give them.

3652. (*Sir J. B. Karslake.*) Have you given us now the most painful experiments that you have ever performed by Mr. Simon's instructions?—I have given you a list comprising injection of pyæmic matter or tuberculous matter into the abdominal cavities of animals, or into the jugular vein, injecting lymph in the skin of sheep, and feeding animals on typhoid dejecta.

3653. Then it has not fallen to your lot at present to perform what you would call a more severe experiment with the knife than that of opening the jugular vein of an animal?—No other.

3654. Now is there any pain caused to a dog in the administration of chloroform?—I think there is; at least we see a great deal of struggling going on in the animal; the animal struggles very hard.

3655. Before it takes effect you mean?—Before it takes effect.

3656. In each of those cases which you have mentioned to me in which you performed the experiments by the direction of Mr. Simon, was it necessary to keep the animal alive after the actual incision or actual injection?—Yes, always.

3657. For how long a time?—Sometimes for weeks, sometimes for days.

3658. Then after the original injection or incision, the pain would be caused by the development of the disease?—Yes.

3659. In those cases, I suppose chloroform would be useless?—Quite so.

3660. As I understand you, if you were directed to perform an operation for the purpose of ascertaining some fact, or supposed fact, with reference to the nerves of a dog, and it became necessary to cut the back of the dog severely for the purpose of exposing the dog's nerves, for the sake of saving yourself inconvenience, you would at once perform that without the use of anæsthetics?—Yes.

3661. And it is only because the dog might howl, or get into contortions, that you would use anæsthetics at all?—Yes.

3662. But it so happens that for Mr. Simon's purposes, at all events, you have never been called upon to perform such an experiment?—Never.

3663. Do I understand you to say, that you have any public class, in contradistinction to the private class you have spoken of, of individuals who attend the laboratory?—No public class.

3664. Then the experiments you perform involving pain to animals are in the presence of certain gentlemen who come to the laboratory for the purpose of learning?—Yes, and altogether there are only three or four such experiments.

3665. How long have you been performing those experiments before a private class?—I may say three years.

3666. Can you tell me in the course of each year how many experiments you have performed before that class involving pain to animals?—Two.

3667. Two in each year?—Yes: sometimes two, and sometimes three.

3668. Will you give us the three which you have performed?—The cauterisation of the cornea of a frog; then the injection into the blood vessels of a frog; then the cauterisation of the cornea of a kitten, but that is done under hydrate of chloral.

3669. That is an anæsthetic?—Yes.

3670. And was that done in that way to satisfy the pupils, or for your own convenience; I am now upon the experiments for teaching purposes?—That was also done for keeping the animal quiet while doing it, and for the pupils convenience, and for mine.

3671. Have you ever enunciated to these private pupils who come before you your view that a physiologist engaged in the research should pay no attention to the pain of animals, but should avoid the use of anæsthetics?—I have never had occasion to speak to pupils of private research, of special research.

3672. As I understand you the case has occurred in your private laboratory? — Not remonstrance exactly. I remember it only once; I said, "I am "going to perform this and that experiment."

3673. Just tell us what it was?—The cauterisation of the cornea of a frog. I said, "Do you object to "that," and only on one occasion I remember one said, "Yes, I think it is useless."

3674. How many pupils were present at that time? I have never more than five or six at a time.

3675. Did you continue to perform the experiment notwithstanding that remonstrance?—No, I did not

Mr. E. Klein, M.D.

28 Oct. 1875.

do it; I do not generally do these experiments for all the pupils at once; because my pupils are not as in a class carried through instruction in the same subject, but every one works in a special subject; and so I do the experiment for one.

3676. But as I understand, the whole number of experiments before every pupil in the class, or every individual, does not exceed three?—I mean three kinds; but the experiment may repeat itself several times.

3677. How many animals are sacrificed, do you suppose, in the course of the year for the purpose of these experiments for teaching your private pupils?—I can say only in a rough estimate. I should not think more than 10 or 12.

3678. And of those, what is the proportion that would be of the lower animals—frogs, for instance?—Frogs are the greatest quantity; one kitten, perhaps, among the whole lot.

3679. You say one kitten; have you only destroyed one kitten in these experiments?—No; I have only made one experiment on a kitten. I have cut off the heads of many kittens, but have made an experiment on a living kitten for teaching purposes only once.

3680. Have you ever made an experiment on a living dog for teaching purposes?—No; I think not.

3681. In the case of frogs, you never take out any part of the brain before you perform these experiments, do you?—No.

3682. That is a short process, is it not?—Yes.

3683. But you think it unnecessary, because you say that a physiologist has a right to do as he likes with the animal?—Yes.

3684. Now in your own private research, what animals have you chiefly used since you have been in England?—Guinea-pigs, rabbits, rats, mice, frogs, dogs, cats, monkeys, and sheep.

3685. But in the case of monkeys, as I understand, that was only for the purpose of ascertaining the effect that food would produce upon them?—Yes, or feeding them with some typhoid stuff.

3686. Can you give me what, in your judgment, was the most painful experiment that in your private research you have tried since you have been in England, the one causing the most pain to the animal; I refer to the actual pain inflicted in the course of cutting the animal?—I do not think I have done any more severe experiment than cutting the skin, and injecting into the jugular vein.

3687. That is the most painful experiment you have performed in England, you think?—That is the most painful experiment I have performed in England in my special research.

3688. I think you have said that you have been engaged in this Brown Institute a little more than four years?—Yes.

3689. Did you come direct from Germany?—Yes, from Vienna.

3690. Have you studied in Germany?—Yes, in Vienna.

3691. What laboratory did you come from?—Professor Stricker's, in Vienna.

3692. How many years had you studied under him?—I had studied only pathology and histology under him about four years.

3693. How many lectures of his did you attend in the course of the year?—No lectures.

3694. Or how many demonstrations?—His laboratory was a laboratory where private researches were carried out, and I being his private assistant was more or less connected with all the experiments that were carried out there either directly or indirectly.

3695. And might I ask you, in the course of the last year that you were engaged as assistant to Dr. Stricker, about how many experiments were performed in his laboratory?—I could not say.

3696. Was the number in hundreds?—No, far less.

3697. What animals did he chiefly use?—Rabbits and dogs.

3698. Not frogs?—Yes, frogs also; that is the physiologist's animal.

3699. However the largest animals he used were dogs and rabbits?—Yes.

3700. Now there was one answer which you gave in the course of the questions put to you in which you said that other physiologists in England take the same view of the subject that you do. Do you know any physiologist that works in his private laboratory except yourself in England?—I think that is more a matter of private talk, is it not.

3701. You have given an answer; I want to know whether you have any accurate information which enables you to say that other physiologists in England take the same view of the subject that you do?—I have no accurate knowledge about it. I only expressed an opinion, a belief. I believe it is so; I could not prove it, and I do not know for certain whether it is so; but I believe that there are other physiologists who take the same view that I do.

3702. (*Mr. Erichsen.*) You make a distinction, I suppose, between physiologists and practical physicians?—Yes.

3703. Of late years there has been a great change, has there not, in that respect in the scientific world in England. Formerly experiments were usually made by practising physicians and surgeons in order to determine some special point in practice?—Yes.

3704. For instance, a man ligatured an artery in order to see what the effect was?—Yes.

3705. But of late years a class has grown up in the medical profession, biologists and physiologists, who do not practice medicine in any way whatever, who may or may not have been educated for the medical profession, but who devote the whole of their time to the study of the laws of life upon animals?—Yes.

3706. And it was to them that your remarks were applicable?—Yes.

3707. (*Mr. Hutton.*) Did I rightly understand you to say that the frogs were always killed after this cornea operation, or only sometimes?—As a general rule they are killed.

3708. You have to excise the cornea, have you not?—Yes.

3709. And if they are not killed what is done with them?—At that time they are generally killed—at least to my knowledge always—but there may be one or two occasions where I have not time to look after them, and I do not know whether my orders are carried out or not.

3710. (*Chairman.*) Do you mean when you say "killed" that the operation killed them?—Before the cornea is cut out the animal is generally decapitated, and then the cornea is cut out from the head.

3711. (*Mr. Hutton.*) Whether that is always so done you are not sure?—I cannot speak with certainty about any one thing, but as far as my knowledge goes it is so.

3712. I take it that the operation of scraping the cornea which precedes, I believe, the injecting into it would be a very painful one to the human being?—Yes.

3713. You suppose that a frog does not suffer as a man in that operation?—Yes, I think it does not.

3714. But you say it would be a painful one; and the frog is killed at the end of an hour, or what period?—I would say 20 minutes.

3715. Is that the English or German frog?—The German frog.

3716. And how long would the English frog be kept alive?—Twice as long.

3717. Have you ever performed in England this operation described in your part of this handbook, at page 108, on the mesentery of a frog?—I have done it.

3718. It would be a much more painful one, would it not?—That is done always under curari.

3719. But it is quite an open question whether curari is, or is not, an anæsthetic for a frog?—I think

Mr. E. Klein, M.D.

28 Oct. 1875.

it is; Schiff made some experiments to prove that it is.

3720. Claude Bernard thinks it is not, I believe ?—Those that believe in experiments will, I think, agree that it is.

3721. But supposing it is not an anæsthetic, this experiment on the mesentery would be much more painful, would it not, than the cornea experiment ?—Well, there is another question necessarily involved in this, namely, how much less would a frog feel if he does not breathe ? The fact is, that the frog does not breathe with his lungs after the application of curari, but breathes only through the large vein of the skin.

3722. And you think that might diminish the suffering ?—I have no doubt it does.

2723. Have you performed this experiment on the mesentery of a frog before your private class, or not ?—I have done it perhaps twice, not before a class, but before persons who were there for teaching purposes. I have done it several times for the purpose of pathological investigation.

3724. You have done it always under curari ?—Yes; it could not be done without it.

3725. You have to keep the creature still, you mean ?—Yes.

3726. And that is the reason of your using it ?—Yes; and even if curari were not an anæsthetic I believe that the frog would undoubtedly feel much less when the breathing is reduced to that very small amount which takes place through the vein of the skin than it does when curari is not applied.

3727. And have you ever done this experiment at page 98, about the injection of small mammalian animals during life ?—I never did that before pupils.

3728. Have you done it in this country for private research ?—I have never done it myself in England; I have done it in Vienna.

2729. Have you ever had to make experiments on arterial pressure in England, in the course of your teaching ?—No.

3730. Can you give me the least idea of about the quantity of animals required for the Vienna laboratory in a year ?—No.

3731. Not even an approximate number ?—No.

3732. Is it a very large laboratory ?—Yes. Professor Striker's laboratory is; the room is small, but the amount of work done there is very great, or it was.

3733. And of course a considerable number of animals are used there ?—Yes, very considerable.

3734. Is it at all as large as Ludwig's laboratory at Leipsic ?—No.

3735. Have you ever studied there ?—No.

3736. You could not give any idea what the consumption of animals there is ?—Not in the least.

3737. Are there any other foreign laboratories that you have studied in ?—No. I have studied only in Professor Brücke's and Professor Striker's, in Vienna.

3738. And Professor Striker's is the larger of the two ?—Yes.

3739. And you think that the view of scientific men on the Continent is your view, that animal suffering is so entirely unimportant compared with scientific research that it should not be taken into account at all ?—Yes, except for convenience sake.

3740. Have you told us everything that is done in the Brown Institute; have you had no inquiries there but what you have mentioned in answer to Sir John Karslake ?—I believe I have not omitted anything.

3741. When regard to any experiments on dogs which you have made, have they been simply cutting the carotid artery or the jugular vein ?—Yes, I think that is all.

3742. There is nothing that has lasted then for any considerable time ?—No; I could not remember now anything else.

3743. I thought I understood you once to say that you had performed on dogs operations that had lasted half an hour ?—Half a minute, perhaps, but not half an hour.

3744. I thought you said operations that might take half an hour, but that they were never done before pupils ?—I do not remember anything of the kind except bleeding a puppy to death by opening the carotid, and that is a matter of half a minute.

3745. (*Sir John Karslake.*) What was that for ?—To draw out as much blood as possible, say for injection of the lymphatics of the lung. That can be done most conveniently, and with best success, by first bleeding the animal to death.

3746. (*Mr. Forster.*) Do you recollect whether Mr. Simon informed you that when I was in office I had said something to him about this, or did he give you a minute that I wrote ?—I think he spoke to me about it; but really it is so long ago that I could not be certain.

3747. You cannot recollect whether he gave you a minute ?—No.

3748. You do not recollect his giving you any words written by me, to this effect, "That no experiments on living animals should be conducted at the cost of the State without the employment of some anæsthetic in case of painful operation, and without a report from time to time by the gentleman conducting the experiments, explaining their object and showing their necessity for the purpose of discovery." Do you recollect seeing those words ?—No. May I be allowed to say this, that at that time I was not connected directly with Mr. Simon. I was at that time simply an assistant of Dr. Burdon Sanderson, so that Mr. Simon could not have occasion to give me that instruction in an official way.

3749. When you were put directly under him you had not that minute laid before you, as I understand you ?—No.

3750. (*Mr. Hutton.*) Have you ever discussed this question of the relation of animal pain to physiological inquiry with Dr. Sanderson ?—I think we did.

3751. And I think that he differs from you on that point ?—Yes; he does differ from me.

3752. But he understands your views on the subject ?—I do not think we have entered very minutely into it; but I remember I had repeatedly occasion to say, "I do not think it is a matter of necessity to administer chloroform in a general way."

3753. (*Lord Winmarleigh.*) You stated just now that you believed that curari was an anæsthetic for certain animals ?—Yes.

3754. What are your reasons for that belief ?—My reasons are chiefly the experiments given by Schiff, he made some experiment, and I think it proves that curari does not act always on the sensitive nerves. We know that it paralyses the motor nerves.

3755. But Claude Bernard says, does he not, that it does not destroy the sensitiveness ?—That was the general belief until these experiments of Schiff's were known.

3756. Have you read Claude Bernard's reasons for his view ?—No, I have not.

3757. (*Mr. Hutton.*) You are perhaps aware that Claude Bernard describes two experiments on man with curari ?—No.

3758. (*Lord Winmarleigh.*) Will you state, as shortly as you can, the exact reason for supposing that curari is an anæsthetic ?—First of all, the reason which I gave to Mr. Hutton, namely, that if you poison a frog with curari you stop the breathing through the lungs, it breathes only through the cutanean vein; and it is quite clear that it does not keep up its vitality, its sensitiveness, to such an extent by the small amount of oxygen it may get through the vein.

3759. Would that destroy sensitiveness ?—It would lower it.

3760. But not destroy it ?—I do not think it would destroy it, but it would destroy it undoubtedly. And then, secondly, I believe, with Schiff, that curari does act as an anæsthetic for this reason. If you ligature, for instance, one artery of the lower limb of a frog and then poison the animal with curari, you will find that the movement of that limb is not destroyed, because curari could not penetrate into the muscles

Mr. E. Klein, M.D.

28 Oct. 1875.

of that region of which the artery has been ligatured. If now you pinch the other leg which is curarised the frog will show movement with the uncurarised limb, because the muscles are not paralysed. If then you paralyse that limb where the curari is not acting on the muscles it does not move the limb. That shows that where the muscles have been paralysed also the sensitive nerves have been paralysed, and that where the muscles have not been paralysed the sensitive nerves have not been paralysed.

3761. Is that movement indicative of pain?—Yes; we take it generally that when we pinch the frog and it does not move it does not feel.

3762. Dr. Schiff practises in Florence, does he not?—Yes.

3763. Is he a large experimenter in physiology?—Yes; from what he has written, and from his researches, I may say, perhaps, that he is one of the largest.

3674. Are you aware whether he uses anæsthetics?—I am not. I could not say.

The witness withdrew.

Mr. Edward Albert Schäfer, M.R.C.S., called in and examined.

Mr. E. A. Schäfer, M.R.C.S.

3765. (*Chairman.*) Are you assistant professor of physiology in University College?—Yes.

3766. Assistant to Dr. Burdon-Sanderson?—Assistant professor to Dr. Burdon-Sanderson.

3767. Now have you paid considerable attention to the subject which has been referred to us?—Yes, I think I may say so.

3768. You have seen such experiments of course as have been performed at University College?—I have seen a good many of them.

3769. Speaking generally, you know what is taking place at University College?—Yes.

3770. What is the practice there with regard to experiments which are painful in their nature, are anæsthetics always employed?—If possible.

3771. And to whatever extent possible, in cases where it is not possible to do it entirely?—Certainly so.

3772. Do I rightly understand you to say that at University College the treatment of animals is dictated by a sentiment of humanity?—Most strictly so; I am quite certain of it.

3773. And that that is the view both of the superior medical gentlemen, those with whom you are associated, and also of the pupils?—I believe it to be so.

3774. Is the proportion of experiments that are painful in their nature very large?—Very few experiments on the whole are done at all.

3775. The principal part of your teaching I suppose is upon the dead tissues?—My own is entirely upon the tissues.

3776. But I mean in the college the experiments are most of them upon the dead tissues, are not they?—The physiological experiments are not on dead tissues; so far as the chemistry is concerned they are entirely.

3777. The experiments in the physiological laboratory are very much upon the dead tissues?—They are certainly upon the tissues, but then those are histological for the most part, and appertain to the branch of the physiological department which has for its object the study of the dead tissues.

3778. What is the department in which experiments are carried on upon the living subject?—That of practical physiology, of which again there are two departments, one in which the professor himself does experiments upon living animals, and shows them to a class; and another department, which is only just springing up, in which advanced students or medical men come to the laboratory and perform experiments on living animals in conjunction with the professor or myself.

3779. Now are almost all those experiments performed under chloroform?—They are almost all performed under some anæsthetic, either chloroform, or ether, or opium.

3780. Is curari, or wurari, treated as an anæsthetic in your laboratory?—No; at the same time we are not fully convinced as to how far it may be an anæsthetic.

3781. And therefore while that question is unsettled, you do not treat it as being so?—Therefore we frequently give opium as well.

3782. Can you tell us what is the whole number of living animals consumed in your laboratory in a year?—I cannot tell you, but it is very small; that is, not including frogs. So far as rabbits and dogs are concerned; of dogs there are perhaps not half-a-dozen consumed in the year; of rabbits a greater number, but not very many. But it depends entirely upon what series of experiments are being performed.

3783. Then with regard to frogs, do you consume a large number of frogs?—Yes.

3784. Are those the English frogs, or frogs imported for the purpose?—Some of them are English frogs, and some of them of the larger kind.

3785. Is the larger kind preferable for all experiments?—For nearly all experiments.

3786. And why is it preferable?—Because the parts are larger for manipulation.

3787. Not because the animal is of greater endurance?—Certainly not; I do not think it is of greater endurance.

3788. Then are the experiments upon living frogs usually performed with or without anæsthetics?—Usually without.

3789. Is no measure taken to diminish the pain of the frog?—The only measure taken is great care in the performance of the experiments; no other measure.

3790. No anæsthetic of any sort is used?—Very seldom indeed.

3791. Is that because you have the opinion that the frog is not so sensitive as the higher animals?—That is my opinion.

3792. And that is the ground upon which the practice rests?—That is the ground.

3793. Have you received your education in England or abroad?—In England; I have studied abroad.

3794. (*Sir J. B. Karslake.*) I understand you to say that sometimes you do administer anæsthetics to frogs?—I have seen them administered; I never do it myself.

3795. Are the experiments which you make upon frogs painful in their character?—They would be if the frog had an amount of sensibility in proportion.

3796. Some of these experiments involve cutting the frog open, do they not, and exposing the lungs, and so forth?—Certainly.

3797. Would the anæsthetic in any way interfere with the experiment in a great number of instances?—We do not know what anæsthetic to apply to frogs; we do not know that the anæsthetic would not give as much pain as the operation itself.

3798. Do you remove the brain of the frog, or partially remove it, before performing the experiment?—Yes, that is very often the case; the spinal marrow is cut across.

3799. Is that done in all cases where it can be done without injury to the experiment, or in most cases?—It is done chiefly in those experiments in which it facilitates the object of the experiment.

3800. Then it is not done from a motive of humanity?—I think not.

3801. Then may I take it that there are a great number of experiments which, supposing a frog to be a sensitive animal, must cause a vast deal of pain, which are not done under chloroform?—There is no doubt about it.

3802. And there is no precaution taken to diminish pain, if it suffers pain?—I think I may say no special precaution.

Mr.
E. A. Schäfer,
M.R.C.S.

28 Oct. 1875.

3803. How long have you been lecturer at University College ?—This is my second year.

3804. Did you study at the college before you became a professor ?—I studied there eight years.

3805. Was this the practice ever since you remember anything connected with the college ?—Yes.

3806. That frogs were as a practice not subjected to narcotics or anæsthetics of any sort ?—Yes.

3807. Now as regards the other animals that are used, are they invariably put under anæsthetics, except where necessarily the operation cannot be performed with the assistance of anæsthetics ?—Quite invariably ; I do not think I have ever done experiments myself in this country on one of the higher animals without anæsthetics.

3808. Is that from feelings of humanity ?—Strictly so.

3809. (*Lord Winmarleigh.*) As to those experiments on frogs, do I rightly understand you to say that they were made in your lectures, or in examinations for research ?—In examinations for research.

3810. And you do not practice upon the frog, as you have described now, in your lectures ?—No.

3811. Does anybody ?—I think Dr. Sanderson may in his *practical* course, but I do not assist him in that, and cannot, therefore, speak positively on the point.

3812. (*Mr. Forster.*) With regard to these experiments which you have made in your own research, were they original or new experiments, or were they repetitions of others ?—Entirely new.

3813. Can you tell me what would be your impression with regard to repeating experiments ; when you would consider it necessary to do it ?—I think it is not necessary just for the sake of repetition ; but if you doubted the result then it would be justifiable to repeat experiments.

3814. What do you think is the practice of physiological investigators ; do they think it desirable to repeat the experiments generally themselves, or do they take them for granted ?—They generally take them for granted, if they have already been corroborated by somebody else, and if the names attached to the experiment are of high rank in physiology. For instance, if a series of experiments have been performed by Professor Ludwig of Leipsic, it would generally be taken for granted that the result is a correct one, I mean to say if a definite result is obtained at all.

3815. If he has published that experiment as satisfying his mind that the result has been obtained, physiological investigators in this country would not think it worth while to repeat it ?—Certainly they would not, I think.

3816. (*Mr. Erichsen.*) I think I understood you to say that the reason why you did not give chloroform to frogs was that you thought that it might give more pain, or as much pain, as the experiment ?—I think it would be a great irritant to the skin of a frog.

3817. You probably know as much as anyone in London of what is going on amongst the younger class of physiologists of the day, and I suppose I am correct in saying that the most active physiological life is amongst those young men of the present day with the exception of a few men, whose names are well known ? —I think so, but I think the younger men as a rule work under the older men.

3818. I was going to ask you whether, knowing well the general habits of the younger physiologists in London, the more active physiologists, you are aware that any of them practice vivisection or experiments on animals for scientific purposes in other places than in recognized physiological laboratories ?—I never saw or heard of such a thing.

3819. I mean in their own houses or in private laboratories fitted up for the purpose, out of medical schools ?—I do not know of such.

3820. The number of physiological laboratories in London is not very large, is it ?—Very limited.

3821. I believe the largest are those of University College and Guy's Hospital ?—And King's College.

3822. And the Brown Institute ?—Yes.

3823. Then it is very easily known, or it could be easily ascertained, how many men are working practically at physiology, how many physiologists in London are working at any given time ?—Very easily indeed, I think.

3824. But then there is another class of men who can scarcely be called physiologists, the medical students still in statu pupillari not qualified practitioners. Are you aware whether they are in the habit of practicing experiments in their own rooms, either singly or associating together for the purpose, or elsewhere than in physiological laboratories ?—I never heard of such a thing.

3825. And you have been for many years as a student and as a teacher connected with one of the largest schools of medicine in London ?—Yes.

3826. And a school of medicine in which physiology probably has been more actively cultivated than in any other school in England ?—I think it has.

3827. So that if it were the case that medical students were in the habit of experimenting either singly or in parties, and in their own rooms or elsewhere than in physiological laboratories, it could scarcely have escaped your knowledge ?—I think it is hardly possible it should have.

3828. In the experiments that are made before students, it is usual to give an anæsthetic ?—I think it is always done at our laboratory.

3829. Have you ever seen an experiment performed before a body of students to which the term "frightful" could be applied with propriety ?—Not one to which I should apply the term " frightful." I have seen formidable experiments, but not without anæsthesia.

3830. I will ask you distinctly, have those experiments been under anæsthetics or not ?—Always.

3831. So that the animal suffered no pain ?—Not the least.

3832. Is it your opinion, from what you know of medical students, that " the more frightful the experiment, the more attractive it is " to the student ?—I have never noticed such a thing.

3833. We were told by an eminent teacher of physiology who has lectured for a great number of years in London, that if he were to perform a painful experiment without anæsthetics before his class, it would probably be repugnant to the feelings of the class ; they might remonstrate, and might leave the room ?—Yes.

3834. Is that your experience also, or would that be your opinion also, if such a thing were done ?—I should not be surprised if some left the room.

3835. Do you think that a lecturer on physiology in one of the large London schools could venture to experiment on animals, performing painful experiments without using anæsthesia, without the risk of a commotion in his class ?—I think there would be such a risk.

3836. But you do not know whether it would be so or not positively, inasmuch as, if I understand you right, you have never seen class experiments of a painful character performed without anæsthesia ?—Not upon the higher animals.

3837. With regard to the frogs, are they frequently pithed, or do they have the brain removed ?—Yes, for certain experiments.

3838. (*Mr. Hutton.*) I understood you to say, that not knowing whether curari was an anæsthetic or not, you frequently gave opium as well. Do you mean that sometimes you do not, that you only give curari in some cases ?—Sometimes we do not, when the opium would act prejudicially to the object of the experiment.

3839. Can you describe to us any experiment in which you would give curari and not opium ?—One would give curari and not opium in certain experiments which might be necessary to make in researches upon the nervous system ; for instance, in researches upon the nerves which govern the blood vessels.

3840. Now in experiments on arterial pressure would you give curari and not opium ?—In some experiments on arterial pressure we should.

Mr.
E. A. Schäfer,
M.R.C.S.

28 Oct. 1875.

3841. And those, I suppose, would be very painful experiments if curari is not an anæsthetic?—Not necessarily so.

3842. I mean they would last a long time?—They might last a few minutes, or they might last an hour or two.

3843. Can you give me any account of the most painful experiment that you have seen used with curari and no other anæsthetic?—I have not had much experience in that way, but I suppose it would be such an experiment as I mentioned just now, an experiment to expose and stimulate the nerves of the blood vessels.

3844. And, I suppose, in stimulating the nerves, there would be a good deal of pain, would there not?—As a rule not, because these are special nerves of the blood vessels, and not nerves of sensation.

3845. Are they motory nerves?—Motory nerves for the blood vessels. In certain cases sensory nerves might also be included.

3846. Now have you ever seen the experiment of bringing the mesentery of a frog out upon a glass plate to show the circulation?—I have often done it.

3847. Would you give only curari for that?—Yes, I think so.

3848. And supposing the frog to be a sensitive animal, that would be a very painful experiment I suppose?—I think the beginning of the experiment would be a little painful, but if done carefully there would be no special pain during the experiment; I doubt if the mere exposure of a serous membrane induces pain in the lower animals.

3849. Do not the experiments on arterial pressure last a long time, many hours?—They may do so.

3850. Did I rightly understand you that you have been studying in Ludwig's Laboratory in Leipsic?—I was there this summer.

3851. But not for any length of time?—I was there for about three months.

3852. Can you give the Commission any idea of the number of animals that would be used in the course of the year in such a laboratory as that?—I cannot give an idea, but it would be a very large number.

3853. Hundreds, for instance?—Hundreds, if you take animals of all kinds; of rabbits and dogs, I suppose more than a hundred.

3854. In the course of a year?—Yes.

3855. And that without counting "the physiologists' animal," the frog?—Without counting the frog.

3856. A witness that we have had lately gave us the impression that amongst medical men abroad there would be a certain amount of contempt for attaching so much importance to the sufferings of animals when any scientific object was in view. Is that your impression or not?—I cannot say that it is my impression; I am perfectly certain that abroad they also think about the feelings of the animal that they operate upon.

3857. They try to economise the pain as much as possible, you think?—I am quite certain of that.

3858. As regards demonstration, are a much larger number of demonstrational experiments used abroad than are used in England that are likely to give pain?—There are not a very large number performed abroad of demonstrational experiments that are likely to give pain, but I think more than in England.

3859. On what do you ground your idea that the frog is not a particularly sensitive animal; have you any scientific reason for that?—One is perfectly certain that the frog at least cannot reason about the sensations that he has; and on that account in itself any actual sensations that the frog feels cannot be looked at in the same light as the pain which the higher animals, which undoubtedly have a certain amount of reasoning power, would feel.

3860. One of our witnesses, a veterinary witness, said that he had observed that frogs were quite as sensitive to parasites as even the higher animals, and appeared to suffer as much from parasites as higher animals, and he seemed to think that was a reason for supposing that frogs did suffer as much as the higher animals. Would you think that that was a reason of no weight?—I myself do not see the weight of the reason; I think it is of no weight.

3861. You think the restlessness and the irritation shown is not any measure of the suffering?—Not necessarily so; for this reason, that a frog will show sometimes more restlessness after its brain is removed than before.

3862. But that surely applies equally to human beings if the spine has been divided?—Unquestionably there is sometimes more reflex action when the man feels nothing than there was before.

3863. So that that rather breaks down the argument in the case of the frog, does it not?—Not altogether; because since there is ordinarily a large amount of reflex action in the case of the frog, it shows that the brain has less power in controlling those reflex actions in the lower animals than it has in the higher animals, and therefore is probably less active in other respects also, in receiving impressions of pain amongst other things.

3864. (*Chairman.*) Then at University College you carry the conviction of the comparative insensibility of the frog to pain so far, that you do not think it necessary to take any precautions to mitigate the suffering that you inflict upon frogs?—We do not take any precautions in the way of anæsthetics. The precautions we take are to so arrange the experiment that it shall involve the least amount of injury to the animal, consistently with the success of the experiment.

3865. But do you remove the brain, or even the head, of a frog in all cases in which it is possible to do so, without destroying the effect of the experiment?—That we certainly do. I may remark that we principally use the frog for three purposes; for experiments upon the heart and circulation, for experiments upon the muscular system, and for experiments upon the nervous system. In the first-named experiments, those upon the heart and circulation, it would in many instances not be allowable to remove the brain, because the removal would cause too great a shock to the animal; but in both the other cases, the experiments on the nervous system and on the muscular system, the frog is almost in all cases killed before the experiment; and frequently the tissues are taken from the dead animal.

3866. Did your answer about the frogs apply to the classes and to demonstration, or to physiological research?—My answer as to the frog with regard to anæsthetics applied to both.

3867. Then you mean that a considerable number of frogs are used in demonstration in the class in the course of a year which are not deprived of insensibility by any proceedings, either the use of anæsthetics or the severing of the connexion between the brain and the part operated upon?—A *few* such are employed for demonstration in the class; a considerable number are employed for research.

The witness withdrew.

JOHN GRAY M'KENDRICK, M.D., called in and examined.

J. G.
M'Kendrick,
M.D.

3868. (*Chairman.*) At the present moment you are in private practice as a physician in Edinburgh?—Yes.

3869. You are also a lecturer upon physiology in Edinburgh?—Yes.

3870. Not, I think, in the university itself?—No.

3871. But in a school which is in some way connected with the university?—Yes.

3872. Will you be so good as to explain to us the precise connection of that institution with the uni-

J. G. M'Kendrick, M.D.

28 Oct. 1875.

versity?—The Extra Academical School of Edinburgh consists of a body of lecturers upon various subjects included in the medical curriculum, whose lectures qualify for graduation at the university, and also for the various examining boards throughout the kingdom.

3873. You were before you occupied this position assistant to the late Dr. Hughes Bennett, were you not?—Yes.

3874. And you have held an appointment within the university itself?—Yes.

3875. What was that appointment?—Assistant to the Professor of Institutes of Medicine.

3876. You have some connection with the Veterinary College, I think?—Yes. I also lecture upon physiology in connection with the Edinburgh Royal Veterinary College.

3877. In those capacities you have had considerable acquaintance with the subject which is referred to us?—Yes.

3878. Will you be so good as to give us the advantage of your experience upon the subject referred to us; namely, how far experiments upon living animals are in your opinion necessary for scientific purposes; and next, what is the mode in which those experiments, as far as you know, are practised in this country?—Probably the better way of giving you that information is to refer you in the first place to a very short paper which I wrote for the British Medical Journal of January 9th, 1875, entitled, "What has "Vivisection done for Humanity?" in which I have attempted to answer the question, what has vivisection done for medical science, by enumerating a number of discoveries which I believe were made by this mode of investigation. These discoveries have regard to the physiology of the nervous system, to the circulation of the blood, to respiration, to the functions of various nerves, and to certain points connected with the physiology of the senses. All of the facts which were discovered by these investigations now form, as it were, the groundwork of the knowledge of all medical men in the detection and treatment of disease; and without, for example, the knowledge which has been acquired by this mode of investigation with regard to the functions of the nervous system, I do not see how it could be possible at the present time for a medical man to make an accurate diagnosis of certain cases of disease. For instance, I may allude here to the discoveries of Sir Charles Bell and Brown-Séquard regarding the functions of the various parts of the spinal cord, and more especially the connection of the upper part of the spinal cord with the base of the brain. Anatomy so far can give information regarding the conditions of certain diseases of the nervous system; but I do not think it could possibly explain the whole phenomena. If, for instance, a man was paralysed on one side of his body, say the right side, without a knowledge of the exact arrangement of the fibres in the spinal cord, and how they cross over to the other side of the brain at the upper part of the spinal cord, I do not see how we could arrive at the knowledge that this paralysis was caused by a clot in the opposite side of the brain from the paralysed side.

3879. One would have supposed that the crossing of the fibres might have been discovered by anatomy?—The practical fact is, that it is extremely difficult, I should say almost impossible, to trace accurately the course of the fibres in the softer parts of the central nervous system. One certainly in the medulla can see indications both to the naked eye, and still better in microscopical sections, of a decussation or crossing from one side to the other; but without actual experimental inquiry, I think that the appearances are so indefinite that we should not be entitled to say that we thoroughly understood the cause or the conditions of the affection. Then with regard to the discoveries more particularly of Brown-Séquard, it is well known that that physiologist made out very distinctly that the posterior fibres of the spinal cord decussated all down the back of that part of the nervous system; and he showed that by making sections, say, into one part of one side of a posterior column, there was no paralysis of motion, but paralysis of sensation upon the opposite side; and on cutting the anterior column he found paralysis of motion upon the same side. Now, what I contend for is, that mere anatomical investigation would not have discovered the exact course of these fibres in the spinal cord. Certainly it is right to state this, that after or about the same time as Brown-Séquard made these investigations, Mr. Lockhart Clarke, of London, made a number of sections of the spinal cord, prepared for observation under the microscope, and pointed out certain decussating fibres. But the whole truth would not have been ascertained by an examination of these sections alone. The experimental evidence had to be conjoined with the evidence derived from microscopical examination. Then I might give somewhat similar instances with regard to the physiology of circulation and of respiration. There is one interesting experiment, for example, which at once gave the physician an intelligent comprehension of the cause of cardiac murmurs sometimes heard over the heart when you apply the stethoscope over that region. Certain experiments were made by the late Dr. Hope, in which he investigated the causes of the sounds of the heart, and he showed that by interfering with certain of the valves experimentally murmurs were produced; indeed he imitated artificially, in a manner, conditions which we know frequently occur in disease. Another remarkable example, I think, of the value of the experimental method in discovering the physiology of a certain part of the nervous system we have in the well-known researches of Dr. John Reid. No doubt there are certain points still not thoroughly cleared up regarding the functions of certain of the cranial nerves; but anyone who reads books on physiology written before his time can see that there was then no correct information regarding the functions of the great nerves issuing from the base of the brain. As an example of bad treatment in consequence of deficient knowledge of the functions of these nerves, we have the well-known instance of section of the seventh nerve, which we now know to be the motor nerve of the face. It was supposed to be a sensory nerve—indeed at one time the distinction between motor and sensory nerves was not thoroughly understood; and the consequence was that for neuralgic affections of the side of the head the seventh nerve was frequently cut by surgeons instead of severing the nerve which conveyed the impressions to the brain and gave rise to the pain. Then, without going through these cases now (I have given a large number of instances in the paper), I may point out a research in which I was personally connected, in which I scarcely think we could have derived any information without experimental inquiry, and that is regarding the problem of the action of light upon the retina,—a problem which is not limited merely to the action of the stimulus upon this single organ, but no doubt has a bearing upon our knowledge of the action of all the senses. This investigation, which was conducted by my friend Professor Dewar, of Cambridge, who recently was a colleague with me in the Veterinary College, and myself, brought out the fact that light produces a change in the electrical condition of the retina, and that this change is transmitted to the brain. I have brought with me a few papers which give a short account of this research. It is a good example, I think, of a purely experimental research—a research of which the results could not have been arrived at either by observation of disease or by anatomical observations. I have another series of experiments to allude to; (I think it better, perhaps, to give as evidence what I am personally acquainted with myself;) I have given in my paper the list of what others have done. I allude now to researches which are contained in the volume I have before me, a volume entitled "Researches "into the Antagonism of Medicines, being the Report "of the Edinburgh Committee of the British Medical

"Association, by John Hughes Bennett." I may say that I did nearly the whole of that work. The object we had in view was to find out whether or not certain active substances exercised a counteracting influence within the body; so that in the first place we might be able perhaps to discover real antidotes for poisons, and in the second place (and I consider this the most important of all) that we might perhaps be able to get upon a track which would lead us to counteracting the effect of the zymotic poisons which are believed to produce the various fevers. This research orginated, I may mention, chiefly in a great desire which Dr. Hughes Bennett had to find out an antidote for opium. Opium poisoning is of course pretty frequent, and at present there is no apparent efficient system of treating the case. A great many observations were made upon this point, without however, I am sorry to say, our being able to find out an efficient antidote for opium. We, however, ascertained an antidote for a very powerful poison, namely, strychnine. Previous to our work this had been discovered by a German, Oscar Liebreich, of Berlin. Here we have an instance of a distinct physiological antagonism, so distinct that if I were called upon to see a man in tetanic convulsions from strychnia poison, I should not hesitate for one moment in at once putting him powerfully under the influence of the hydrate of chloral. I know of one instance which occurred in the practice of a friend of mine, Dr. Angus M'Donald, of Edinburgh: he had given a patient strychnine as an ordinary remedy for a nervous affection; the man had unfortunately taken too much,—he had not taken an excessive dose apparently, but probably there was a predisposition to the remedy having a more powerful effect upon him than upon others; he was brought in a cab to my friend's door in a partially rigid condition; he was passing into the rigid tetanic convulsions characteristic of strychnia poisoning; Dr. M'Donald had seen the experiment in the physiological laboratory of the University of Edinburgh of rabbits being submitted to the action of both poisons, and he was so convinced of the powerful efficacy of hydrate of chloral that he took the man into his study and administered the substance in various doses; and kept him there for six or eight hours, when the man went home tolerably well. I give this as an instance of a practical effect resulting from purely physiological investigation. This is one of the most striking instances, I think, that I could possibly give of the value of experimental research. You may give a rabbit of, say, three or four pounds weight the 60th part of a grain or the 40th part of a grain of strychnine; it will die probably in one tetanic convulsion in the course of perhaps 10 or 15 minutes. Give another rabbit of equal weight and apparently of equal strength the same dose, followed by a dose of from 15 to 20 grains of the hydrate of chloral, it will lie quite quiet, breathing calmly; perhaps there may be a few convulsive twitches, but there is a very strong probability that it will recover entirely. In this investigation, too, we also directed our attention to other antagonisms. We repeated, for instance, some of the remarkable experiments of Dr. Thomas Frazer, now of Knutsford in Cheshire, upon the antagonism between sulphate of atropia and the Calabar bean; and we found that he was perfectly correct in stating that there is a true physiological antagonism between these two active substances. So that here again in a case of poisoning by Calabar bean, which sometimes has happened, I should have no hesitation in ordering sulphate of atropine. We found also that hydrate of chloral was an antagonist to the Calabar bean, even to a greater extent than sulphate of atropia. The other part of the investigation was certainly not so satisfactory. We devoted a great deal of time and trouble to finding an antagonist for opium, but in that we did not arrive at very good results.

3880. You give these instances to show that important results are frequently attained by experiments on living animals?—Yes.

3881. Now were these experiments largely tried on living animals?—Yes, they were tried to a considerable extent.

J. G. M'Kendrick, M.D.

28 Oct. 1875.

3882. Was this experiment upon the eye you speak of a very painful experiment?—No, it was not.

3883. Were the experiments you tried upon the rabbits by poison very painful?—In some cases I have no doubt they were painful.

3884. (*Mr. Forster.*) How long would the pain last?—In the case of strychnia poisoning, for instance, I would never allow an animal to have a series of spasms from strychnine; I would kill it and not allow it to suffer pain for a lengthened period; but I have no doubt in giving strychnine that there is a powerful tetanic convulsion in which there is a time of pain.

3885. How long?—Sometimes a few minutes. In the case of strychnia poisoning, the symptoms do not make their appearance until almost immediately before the spasmodic attack; the animal may be running about or eating its food, and suddenly it becomes convulsed, and dies usually at once.

3886. Now for the purpose of showing the operation of strychnine proper, is it necessary to have any more experiments?—No, I do not think so.

3887. That is established?—Yes.

3888. The object of these particular experiments was to try whether hydrate of chloral would not prove an antagonist to strychnine?—Yes.

3889. Which you have established?—Yes.

3890. And you do not consider it necessary to repeat that?—No.

3391. In the school in which you are now lecturer do you repeat these experiments for the purpose of demonstration to the pupils?—I did so on one occasion; I should not consider it necessary to do so now.

3892. And if not necessary, I presume not justifiable?—In certain circumstances I might repeat some of the experiments. For example, take an instance of this kind: if I were a Professor of Physiology, and I wished a student to investigate, say, such a disease as tetanus, I should consider it my duty in the first place to let him see tetanic convulsions in a rabbit, but I would not, as a rule, show it to a large class.

3893. Do you in the University of Edinburgh encourage students to perform experiments themselves?—No.

3894. Then if any student performs an experiment of this kind, it is under the direct control and superintendence of the principal lecturer?—It is.

3895. Do I rightly understand that the practice in Edinburgh is to regard the infliction of pain upon animals as a great evil?—I personally regard the infliction of pain upon animals and pain generally as a great evil.

3896. An evil only to be compensated, in your opinion by some great advantage?—Exactly.

3897. In most of the experiments that are performed for the purpose of demonstration we have been told that anæsthesia may always be induced without any prejudice to the success of the experiment?—In my own experience, I may say that I have performed very few experiments for purposes of demonstration in which anæsthetics are required. I do not wish to lay it down as a rule for my brother physiologists, but I am content with showing students, for instance, the physiology of the nerves and muscles, the physiology of the heart, certain facts regarding respiration and the action of the heart upon a frog after the animal has been deprived entirely of sensation by the removal of the head, which is done instantly. I also demonstrate the circulation of the blood in the same animal under the microscope.

3898. Then you confirm the opinion that for purposes of demonstration to pupils, by one mode or another, any experiments upon living animals may be performed under anæsthetics?—Yes.

3899. Now for original research is it often necessary to resort to experiments which cannot be performed under anæsthetics?—No, I do not think so, in my own experience, with the exception of researches

J. G. M'Kendrick, M.D.

28 Oct. 1875.

into the actions of drugs. It is quite evident that there it would not do to complicate matters by administering another substance.

3900. But where you have tried experiments upon such poisons as strychnine, I understand you that there is no prolonged torture of the animal?—No; there might be; it would depend, of course, upon the humanity of the investigator.

3901. But with a proper feeling on the part of the investigator, there would not be?—No.

3902. And that proper feeling, in your opinion, ought, I presume, to be observed?—I think it ought.

3903. And there would be no loss to science if that feeling were always observed?—I do not think there would be any.

3904. Then in other experiments (I am now speaking of original research), where pain cannot be altogether avoided, it may be very much mitigated?—It may.

3905. And it may be that in an experiment the whole of which cannot be altogether free from pain, the most painful portion can be done while the animal is insensible to pain?—I should say in most cases. In most of the researches in which I have been engaged that is quite so. For example, in those researches upon the eye we never experimented upon any warm-blooded animal except under the influence of anæsthetics; and in our earliest experiments we first worked with the eye of the frog after the animal had been killed. And I may mention the following fact as a striking example of how, when science advances, vivisectional experiments may become less required than they are at present. We thought at first that it was necessary to remove the eye of the frog and place it upon our apparatus in order to detect the action of light upon it by means of a delicate galvanometer. After having found that out, we had next to convince ourselves that this impression was carried from the retina to the brain,—that required certain vivisections which were performed under anæsthetics. After that had been done we investigated the transmission of this effect to various parts of the brain,—that was also done under anæsthetics. But latterly, within these last six or eight months, we have been able to prove this remarkable fact, that if we place our apparatus in connexion with the eye of the animal uninjured, part in contact with the surface of the cornea, the other part of the apparatus in contact with a small abraded surface of the skin, (the least thing possible, where the hair is merely stripped off, for example,) we still can obtain the effect.

3906. So that in that case nothing to be called pain is inflicted?—Nothing; but that result was obtained after and in consequence of our previous experiments.

I may also be allowed to mention another research in connexion with my own work. Various anæsthetics are used by physiologists; chloroform by some, hydrate of chloral by others, and many use woorara, regarding which there is a difference of opinion as to whether or not it has any anæsthetic properties. Professor Dewar and I entered upon an investigation upon the physiological action of a number of substances which are made by the action of potash upon quinine or strychnine. These substances are known to chemists as the chinoline bases. We have here a series of bases which differ from each other by slight chemical differences, increments of carbon and hydrogen; and we proceeded to investigate the physiological action of these substances from the simpler ones to the more complicated ones, in the hope that we might possibly come upon some of the higher ones that would have an action upon a living body analogous to that of sulphate of quinine, which no doubt would be a very important discovery. During this investigation we ascertained that one of the substances, termed chinoline, has a very remarkable effect upon the living body of the mammal. It differs from woorara in not paralysing the nerves or nerve-terminations distributed through the body, neither sensory nor motor, I believe, but it acts principally upon the nerve-centres, the various ganglia of the brain; and it is remarkable that it does not act to a great extent upon the respiratory centres. So that where it is administered to a rabbit, say three grains to an animal of four pounds weight, the animal becomes completely unconscious, and still respiration goes on: the animal is fit for any kind of observations that may be necessary. I am convinced that in that case there is no feeling of pain.

3907. Now has this substance ever been tried upon the human being at all?—It has; I tried it upon myself by swallowing some.

3908. Were you insensible to pain?—I may explain that the difficulty with reference to the higher animals, and what deprives it no doubt of its value in the meantime, is that it at first excites nausea and vomiting. If it did not excite severe nausea and vomiting, I have no doubt it would be a most important substance; chinoline, I believe, will ultimately replace woorara in physiological laboratories in many experiments.

3909. But you did try it upon yourself?—Yes, I did.

3910. Was any pain inflicted upon you while under it?—I was not able to take sufficient to produce the anæsthetic effect because I got so sick; but we attempted it upon a dog and upon a monkey. It was quite sufficient to do it on those two; and we saw at once that there was a great practical difficulty with regard to its application in the higher animals.

3911. (*Mr. Forster.*) Was it injected?—Yes, a small quantity injected.

3911*a*. You have not tried injecting it on a human being?—No, I swallowed the doses administered to myself.

3912. Would there be a difficulty in injecting it?—There would be a difficulty in getting it in a sufficiently concentrated solution.

3913. (*Sir J. B. Karslake.*) It caused vomiting in the monkey, did it?—It caused vomiting in the monkey although injected, and it is quite evident it was not applicable; it is a remarkable fact that where we had the more highly developed brain it caused this action, but in the rabbit, the guinea pig, the hedge-hog, the bird, the mouse, the rat, the frog, and the fish it had the effect I have just mentioned of an anæsthetic, without interfering with respiration.

3914. What is it?—An artificial production, which may be made by the action of caustic potash upon quinine or strychnine. But I mentioned this research not on account of its intrinsic importance, but by way of showing the practical aim which we had in working, namely, to try if possible to work up to a high base like sulphate of quinine, which would no doubt be very valuable; because chinoline can be made from substances which exist in coal tar.

3915. (*Chairman.*) Then I collect that in your experiments on frogs you treat them as animals that have sensibility, and you do not operate upon them under the hypothesis that they have no sensibility?—No, certainly not. I can show a great many phenomena connected with the muscular system, the nervous system, the action of the heart, and the action of the skin, without subjecting the animal to anything more than instantaneous pain,—killing it. There is one fact that I should like to mention to you. It has been stated, or rather there was a suspicion abroad, that students have engaged largely in vivisection. During all the time that I have been connected with the Edinburgh Medical School only one instance has come under my own observation. That was the case of a student in the infirmary who had been performing certain experiments upon a cat. I heard of it, and I considered it my duty to go to him and tell him that he should not do it, that he was working at random, and that if he had any proper ideas that might be of value he might come over to the laboratory and speak to me about it; and I succeeded in stopping his experiments. That is the only instance I ever knew, with the exception of students studying the circulation in the web of a frog's foot under the microscope.

3916. Will you have the goodness to put in the

J. G. M'Kendrick, M.D.

28 Oct. 1875.

paper to which you have already referred as having been written by you in the British Medical Journal?—Yes. It is as follows: "What has Vivisection " done for Humanity?—Recent circumstances render " it desirable that some attempt should be made to " answer the question whether or not the practice of " making experiments on living animals has materially " aided the progress of medical science. To answer " this question with completeness would involve an en- " cyclopædic investigation of the sources and history of " our present knowledge. It would be a work into " which a great fund must be brought of patience, " time, and labour. We shall, however, endeavour " to present here at once and hastily some leading " data, such as may be gathered from a cursory review " of the subject. We offer them as *mémoires pour* " *servir*, and shall hope to be able to finish the picture " by filling these rough outlines as time and circum- " stances will permit. We invite assistance and criti- " cism from physicians, surgeons, and physiologists. " We present to-day a first contribution in the follow- " ing skeleton sketch. What has vivisection done for " medical science? A. *It has succeeded in advancing* " *our knowledge of physiology, by*, (1.) Discovery of " the two classes of nerves, sensory and motor, by Sir " Charles Bell. (2.) Discovery of the functions " (motor) of the *portio dura* of the seventh pair, by " Sir Charles Bell. Previously to this discovery, the " *portio dura* was often cut by surgeons for the cure " of neuralgia! (3.) Discovery of the functions of " the anterior and posterior roots of the spinal nerves, " by Sir Charles Bell. (4.) Discovery of the func- " tions of the anterior and posterior columns of the " spinal cord, by Brown-Séquard and others. (5.) " Discovery of one of the functions of the cerebellum " in co-ordinating muscular movements, by Flourens " and others. (6.) Discovery of the functions of the " grey matter on the surface of the cerebral hemi- " spheres as connected with sensation and volition, by " Flourens, Magendie, &c. (7.) Discovery of the " motor functions of the grey matter covering certain " convolutions in the anterior part of the cerebral " hemispheres, by Hitzig, Fritsch, Ferrier, Gudden, " and Nothnagel. (8.) Demonstration of the cir- " culation of the blood, by Harvey. (9.) Measure- " ment of the static force of the heat and discovery " of other hydraulic phenomena of the circulation, " of Stephen Hales, Ludwig, &c. (10.) Discovery " that atmospheric air is necessary to the maintenance " of life, and that, when stupefied by its withdrawal, " animals may be resuscitated by readmitting it, by " Robert Boyle in 1670. (11.) Discovery that atmo- " spheric air by continued breathing becomes vitiated " and unfit for respiration, by Boyle. (12.) Dis- " covery that the air was not only vitiated, but also " diminished in volume, by the respiration of animals, " by Mayo in 1674. (13.) Discovery of the relation, " as regards respiration, between animal and vegetable " life, by Priestley in 1722. (14.) Great discoveries " by Lavoisier on the physiology of respiration, from '1775 to 1780; namely, that respiration acts only on " the respirable portion of the air, or oxygen, while " the remainder, nitrogen, is entirely passive in the " process; secondly, that when animals are confined " in a limited space they die when they have absorbed, " or converted into carbonic acid, the greater part of " the oxygen, and so reduced the air to the state of " an irrespirable gas. (15.) Numerous facts in the " physiology of digestion, observed by Blondlot, " Schwame, Bernard, Lehmann, and others, by ex- " periments on animals. (16.) The discovery of the " functions of the lacteals, by Colin, Bernard, Ludwig, " and others. (17.) The discovery of the functions " of the eight pair of nerves in relation to deglutition, " phonation, respiration, and cardiac action, by John " Reid and others. (18.) The discovery of the func- " tions of the sympathetic system of nerves, by Pour- " four du Petit in 1727, Dupuy in 1816, Brachet in " 1837, John Reid and Brown-Séquard. (19.) The " discovery of the phenomena of diastaltic or reflex " action, by Marshall Hall. (20.) The discovery of the " action of light on the retina, by Holmgren, Dewar, and " M'Kendrick. (21.) The discovery of the glyco- " genic function of the liver, by Bernard, Macdonnell, " Pavy, &c. (22.) The discoveries of the whole series " of facts in the domain of electro-physiology, by " Matteucci, Du Bois-Reymond, Pflüger, and many " others. These discoveries have important practical " bearings. B. *In aiding medicine and surgery.* " (1.) The transfusion of blood and introduction " directly into blood of medicines; first proposed by " Robert Boyle in 1665. In 1665, Sower trans- " fused blood from vessels of one animal into " those of another. First done in human being by " Dennis and Emmerets in France in 1666. Blun- " dell's celebrated experiments on animals in 1818, " since done by many others,–Dumas, Milne-Edwards, " Dieffenbach, Bischoff, Doubleday, Brigham, Waller, " Burton Brown, Klett, Lane, Lavy, Berard, &c. " (2.) Artificial respiration. Vesalius showed that " by blowing up the lungs with air, after the chest " was opened, stoppage of the heart's action might be " delayed for some time. Hook in 1664 first demon- " strated the possibility of artificial respiration. " Brodie, Hope, Le Gallois, Wilson, Philip Marshall " Hall, and Silvester have practised it on human " beings. (3.) The causes of the cardiac sounds have " been determined entirely by vivisectional experi- " ments. (4.) Phenomena of the circulation within " the cranium examined experimentally by Kelly, " Burrows, Reid, &c. (5.) Hunter's operation for " aneurism was first demonstrated and tried on living " animals. This he did in 1785. He also found by " experiments on animals that in many cases the " arterial coats were diseased immediately above the " aneurism, and that consequently it was necessary, in " order to avoid secondary hæmorrhage, to place the " ligature higher up. (6.) The office of the perios- " teum in regeneration of bone has been demon- " strated experimentally by Du Hamel in 1740, " Hunter in 1772, Syme in 1837, Wagner in 1853, " and Leopold Ollier in 1858. The practical im- " portance of these observations is recognised by all " surgeons who have had much to do with diseases of " bones and joints. (7.) The researches of Redfern " into disease of cartilage. (8.) The researches of " Stricker, Cohnheim, Von Recklinghausen, and " many others on inflammation, more especially of " cornea and serous membranes. (9.) Without vivi- " section experiments, we would know almost nothing " of the phenomena of inflammation. (10.) Experi- " mental inquiries into many zymotic diseases, showing " occurrence of micrococci. C. *In advancing thera-* " *peutics, relief of pain, &c.* (1.) Use of ether. " (2.) Use of chloroform. (3.) Chloral, discovered " experimentally by Liebreich. (4.) The actions of " all remedies are only definitely ascertained by ex- " periments on animals. (5.) Action of Calabar bean, " by Fraser. (6.) Antagonism between active sub- " stances and the study of antidotes, many observers. " The above are simply examples which have readily " occurred to the mind. To record all the facts given " to physiology by experiments on animals, would " simply be to write the history of the science. Thera- " peutics is yet in its infancy; but nearly all the facts " definitely known regarding the actions of remedies " have been gained by experiments on animals. To " stop experiments on animals would as surely arrest " the progress of physiology, pathology, and thera- " peutics, as an edict preventing the chemist from " the use of the retort, test-tube, acids, and alkalies " would arrest the progress of chemistry."

3917. (*Lord Winmarleigh.*) I see you divide the subject into three heads, and in the first head, relating to the advancement of knowledge of physiology by means of vivisection, there are 22 instances of the benefits derived to human beings?—Yes.

3918. I presume that does not include the whole number?—No.

3919. Then are there other experiments of great importance which are not included in that list?—I think that I have mentioned the most important

J. G. M'Kendrick, M.D.

28 Oct. 1875.

which I remember. I prepared that list with very great care at the time, and none besides occur to me at this moment. There may be some that I have omitted, but I think I have got in my list the more important facts that you will find in any work on physiology.

3920. Do you make the same observation with regard to the advancement of therapeutics and the relief of pain ?—No. I have no doubt there are a great many more there. I mention at the end of my paper, I think—at all events I should do so now—that the correct knowledge which we have of the action of almost any drug in use and practice has been derived by work of this kind.

3921. Almost all the instances were derived by vivisection, do you mean ?—Almost all derived by experiments on animals.

3922. May I ask you with regard to this new anæsthetic, the hydrochlorate of chinoline ; you have stated the successful experiments that have been made upon that ; have those experiments been recognized by the profession generally ?—They were published in the Proceedings of the Royal Society some months ago, and specimens of the substance have been given to a number of physiologists. I have no doubt they will be making up their minds about it. It has certainly not yet come into general use.

3923. When was the experiment made ?—It would be about the end of last year.

3924. What is the time that is usually occupied before a new discovery of this kind does come practically into operation in the medical world ?—That depends upon various circumstances. I should say that this substance has not commended itself to the profession, because unfortunately it has been found at present, inapplicable in the case of a human being inasmuch as it excited nausea and vomiting. If we had been able to say, "Here is something which has "these effects, without exciting nausea and vomiting," I have no doubt whatever it would at once have excited great attention. It has interested physiologists, both in this country and abroad.

3925. We should not therefore in this Commission be justified in saying that that is a discovery of a substance which for the future can be used as an anæsthetic in the experiments made upon frogs and the lower animals ?—I should think that you would be quite justified in stating that it is serviceable in experimental inquiries upon all animals under the grade, say, of the rabbit,—rabbits, pigeons, rats, mice, frogs.

3926. But still we should not be justified in saying that that is a material recognised by the profession ?—No, I cannot say that.

3927. You merely look upon it as a physiologist ?—I look upon it merely from my practical experience of it.

3928. And you do not look upon it that the results are perfect at the present moment ?—I am certain of the results as regards these lower animals, but it must be probably conjoined with other substances before it can be of use in the case of man and the higher animals. This is still for experimental enquiry. A precaution which I think should always be taken in the case of observations of this kind is, that after any point has been ascertained clearly, it should be shown to a few competent observers, so as to be stamped with authenticity, by their names. This was done, to give a notable example, almost invariably by Dr. John Reid. You will find in the record of many of his experiments that he said, "So and so ; "Professor Alison and Professor Syme were present."

3929. But this is a discovery that has been made very recently ?—Very recently.

3930. And do you believe that discoveries of equal importance to that have been more frequent in these latter times than they were formerly ? — I believe so. I believe we are coming upon a time just now when a great many discoveries will be made.

3931. Your reason for saying that is, that you have witnessed the rapid progress that has been made in these particular instances ?—Yes, and I also have been watching with great interest what Professor Burdon-Sanderson and others have been doing with reference to experimental pathology ; I regard their work as of the highest importance.

3932. I understood you to say to Lord Cardwell that you believed the greater part of these experiments could be made without the infliction of pain upon the animals ?—Yes. There are certain experiments in which you cannot entirely avoid a little pain ; for example, injecting a little of something underneath the skin ; one would not give an anæsthetic to an animal before doing that.

3933. Are you enabled to state to the Commission that you believe that the great majority of the experiments which have been stated to inflict the greatest pain upon the animal may be made under anæsthetics, and without cruelty to the animal ?—I think myself that the majority of the experiments necessary for demonstrating physiological facts can be done with the animal in anæsthesia ; and also in many cases for investigation. For example, in the case of some of those experiments upon the eye, I would have considered myself quite unjustified in performing these experiments upon an animal not anæsthetised unless there had been a great probability of success, judging from results obtained in anæsthetised animals ; that is my feeling. I do not experiment on living animals with or without anæsthetics at random.

3934. We have had some evidence that it is very difficult to perform experiments upon the liver and kidneys without pain to animals ; is that your opinion ?—I have no practical experience regarding that, but I have seen it stated that anæsthetics so affect the function of the liver itself as to vitiate the conclusions. But with regard to that view of the matter I may be allowed to say that the great art in experimenting is to notice the prominent conditions ; the problem of what is the precise effect of an experiment on a living animal is extremely complicated ; there are many factors in it. In some cases I believe one could make a certain allowance for an anæsthetic effect ; that is to say,—supposing you are experimenting upon the liver of an animal : it is a very difficult and serious operation ; in the first instance, no doubt it would affect the nervous and other functions of the animal, and one would not be entitled to say, perhaps, that suchand such effects were entirely due to such and such a substance introduced into the liver ; one would require to take all the facts into consideration, not simply the introduction of this one substance ; therefore I say that in some of these cases (though the particular instance would require to be left to the judgment of the physiologists engaged in the research) one might make allowance for the use of an anæsthetic, and thus save the animal from pain.

3935. (*Chairman.*) In performing such an experiment as that, as I understand you, you must disturb the animal one way or the other ?—Yes.

3936. If you give it great pain you disturb it in that way ?—Yes.

3937. And if you take away pain by an anæsthetic, you cause another disturbance ?—Yes.

3938. So that it may be that in some cases, by not administering an anæsthetic, the animal is not only unnecessarily troubled, but the scientific result is not equal to what it otherwise would have been ?—Yes, in some cases, but that must be left to the judgment of the physiologist investigating it,

3939. (*Lord Winmarleigh.*) This paper of yours I see was published in January ?—Yes.

3940. Since that period have there been any criticisms upon the paper you have put forward, in any of the public journals in Edinburgh or elsewhere ?—I have not seen them in any journal myself ; some one told me that he had seen a criticism or some observation about it somewhere, but I have no distinct recollection of it. I certainly did not see it.

3941. (*Mr. Forster.*) Taking these instances of the advantage of vivisection, I do not ask you whether the majority of those discoveries were made with the administration of anæsthetics, because I am aware that a good many of them would have been made before anæsthetics were introduced; but do you think that if they had to be made now the majority of these results could be obtained with the administration of anæsthetics?—Certain of those facts regarding the nervous system I do not think could have been ascertained with the use of anæsthetics.

3942. But that is only one branch?—That is only one branch.

3943. (*Chairman.*) Those discoveries relating to the nervous system were due chiefly to Sir Charles Bell, were they not?—Chiefly to Sir Charles Bell.

3944. Was he not one of the most humane of investigators?—He was. With regard, for instance, to determining the sensibility of a particular nerve, that could not be ascertained if the animal were completely anæsthetised, but it might be ascertained though the animal was not *completely* anæsthetised: it might be brought under the influence of an anæsthetic to a certain extent. With reference to the eighth pair of nerves, what I say as to investigations of that kind is this, that those investigations no doubt caused a great deal of pain and suffering; but it was done so carefully, so elaborately, by John Reid, and the results were shown to so many skilful men, as to collect such an enormous number of facts that I do not consider it necessary to repeat those experiments.

3945. (*Mr. Forster.*) I see that you have put under the head of the necessity of vivisection for therapeutics, the use of ether and the use of chloroform?—Yes.

3946. Could you tell us how far it was necessary to try experiments in their case—take chloroform?—With regard to chloroform, Sir James Simpson searched about for some time for an anæsthetic—he tried a great many substances on animals, on his assistants, and on himself; he got chloroform I believe from a chemist in Liverpool, and discovered its properties by experimenting in that way on himself and others, and on animals too.

3947. Do you think that he could have got at his results if he had been unable to try it on animals?—Yes, it is possible he might; but I do not think a man would be justified in trying various substances upon himself first until he has tried them several times upon animals.

3948. But would there not have been this danger, that in trying them upon a human being he would have been obliged to limit the extent of his experiment to a greater extent than in the case of an animal?—Yes.

3949. Supposing there had been a prevention of trying experiments upon animals, do you, or do you not, think that the discovery of chloroform would have been delayed?—I think it would probably have been delayed.

3950. And I suppose that those experiments did require some pain to be inflicted, because you had to search about and find out whether the animal showed a sensation of pain?—Yes. No doubt pinching, pricking, and various irritations of that kind; and there was all the disagreeable nausea that often follows inhalation of chloroform. I never had a conversation with any one immediately concerned with these investigations of chloroform; but I think that Simpson performed many experiments upon animals too. Dr. Matthews Duncan, of Edinburgh, was his assistant at the time, and I believe he took chloroform.

3951. (*Lord Winmarleigh.*) Was laughing gas amongst the number?—Yes; he tried a great number of substances which might be expected to produce anæsthesia. Sir James was on several occasions very ill indeed from his experiments, as I have been informed.

3952. (*Chairman.*) But these experiments which you are now speaking of were not of an agonising kind?—No.

3953. (*Mr. Forster.*) I understand that you have before stated in your answers to questions, that you would not try any experiments upon an animal that would give pain without anæsthesia, if you could do it in that way without spoiling the success of the experiment?—Exactly.

3954. And that you would not repeat a necessarily painful experiment unless you thought it was absolutely necessary for verification?—Yes.

3955. Do you see any objection to such legislation as would cause other inquirers to conduct their investigations in the same humane manner as you do your own?—I scarcely see how legislation would have any distinct beneficial effect. I have thought over that matter; various forms of legislative recommendations have come up to my mind, but all of them have certain difficulties about them. For example, having experiments done only in licensed places. Well, there is one objection to that, that it necessitates an observer or inquirer—one who wishes to do something to advance science—to go to that place, and to communicate his ideas and plans to the men in charge of that institution; and one who is earnest in investigating truth should not be subjected, I think, to having to do that.

3956. Have you had the opportunity of reading a Bill brought in by Dr. Playfair in the last session?—Yes.

3957. That, as you are aware, contemplated the licensing of persons rather than of places?—Yes; I think that would meet my view—licensing of persons, not of special places, or of special investigations.

3958. (*Chairman.*) But to licensing persons you would not object?—No, I do not see any great objection to that.

3959. If you knew that there were persons practising in this country who openly avowed that the sufferings of animals were no sort of concern to a physiologist, you would think it reasonable that such people as those should be restrained?—From my point of view I certainly think so; I do not take that view of it at all.

3960. (*Sir J. B. Karslake.*) Have you a private laboratory yourself?—Yes, I have.

3961. And do you find that it is a matter of convenience to you to be able to perform these experiments in your private laboratory?—I do.

3962. Do you think that any legislation interfering with that course would be objectionable?—In what way interfering?

3963. Which should compel every person engaged in physiological research to go to some public and licensed laboratory for the purpose of making his experiments?—I certainly would object to that.

3964. You find it necessary to perform your experiments at odd times, and at convenient moments to yourself?—Yes.

3965. You are a practising physician, as I understand, in addition to lecturing?—Yes.

3966. Now you have spoken about certain experiments that are made before classes; do I rightly understand you to say that for purposes of demonstration before students, no experiments are ever made on a living animal for the purpose of showing the effects of poison by you?—I have shown such experiments. I have shown students the action of hydrate of chloral and strychnine. I must say that my feeling is (I would not run very strongly against other people's feelings in such a matter), that it is an important matter to show a number of students the antagonistic influence, for instance, of two such substances as strychnine and chloral. The thing is so marked, and produces such an impression on the mind, that it could not fail in prompting them to give hydrate of chloral in cases of strychnine poisoning, or cases of tetanus.

3967. As I understand you, you do show the effect of strychnia to students of the higher class in private classes?—Yes.

3968. Now do you think it necessary to show the higher class of student the effect of strychnine on the body of the living animal, in order to assist him, and make him perfect in his learning upon that subject?

J. G. M'Kendrick, M.D.

28 Oct. 1875.

—Yes, I think so; I think in the case of strychnia poisoning, he should see it.

3969. That a tetanic convulsion is so peculiar that it cannot be explained by reasoning, but must be actually seen?—I think so.

3970. You stated that you had something to do with the Veterinary School in Edinburgh?—Yes.

3971. Are experiments on living animals made for the benefit of students in that school?—Not at all.

3972. Have you engaged in physiological research at all with a distinct view to the remedies to be applied to animals?—No; I cannot say so, except that with regard to the investigations I have mentioned, so far as they may benefit the animals, they are useful in that way. I have only been connected with the Veterinary School during one year. I had relief of pain and the cure of disease in view in most of my physiological work, with the exception of the research on the eye which is a purely scientific investigation.

3973. As far as you know, have these experiments on living animals ever been exhibited in the Veterinary School?—So far as I know, they have not. I have heard it spoken of, but I have seen nothing of it; and I can certainly say it is not done at present,—not since I have been connected with it.

3974. I dare say you have a very large number of students under your control in the course of the year, either in public or private clases?—Yes.

3975. Has more than one case occurred in which you have had to remonstrate with a student for the practice of carrying on vivisection in his own house?—No, only one.

3976. Was it stopped on that occasion?—It was.

3977. Have you as good means of knowing as any man can have, whether that practice is carried out at Edinburgh?—I think I have.

3978. And in your judgment it is not resorted to by students?—I do not think it is resorted to by students to any extent. I think if it were I should hear of it, as I heard of that case.

3979. You have stated that that is so with regard to students; now, in your opinion, are young medical men, who have passed beyond the period of studentship, in the habit of practising these vivisections?—No; not in the habit of doing so.

3980. Then you think that it is confined practically to the laboratories, where students are admitted sometimes to take part in the experiments, under the supervision of the experimentor?—Yes, it is practically limited to that.

3981. (*Mr. Forster.*) Do you think it is the habit of students to try those experiments while preparing the theses which they write?—I think they always do so, so far as my own experience goes, under the supervision of the teacher.

3982. (*Sir J. B. Karslake.*) Is it necessary to some extent to have a laboratory fitted up for the purpose of carrying out these experiments?—It is.

3983. And would it be difficult for any ordinary medical man or student to carry them out in his own room without having a laboratory?—It would; the apparatus is very expensive, and during the last 10 or 12 years experimental methods have been introduced quite different from those employed hitherto; the expensive apparatus of the laboratory is necessary for most of these. I could imagine certain investigations being carried on at home, but very few.

3984. Am I right in thinking that in your profession where a person does engage in physiological research, if he discovers anything he is very quick in giving his discovery to the profession?—Yes; as a rule he is anxious to bring it before the notice of the profession as quickly as possible.

3985. (*Mr. Erichsen.*) Your attention has chiefly been directed, I think, to experiments of a toxicological and therapeutical character?—Yes, chiefly to them; but I regard my principal work as being in connexion with the eye investigations.

3986. And they were in the domain of pure science?—Pure science.

3987. Am I right in concluding, from what you have stated to us, that you think we shall not advance very much further in our knowledge of therapeutics and in toxicological inquiries except through the medium of experimentation?—I certainly think so.

3988. That we have arrived at a sort of finality in the old method of investigation of the action of drugs and poisons?—Yes.

3989. That very important results, directly beneficial to humanity, have already flowed from the experimental method of investigation?—I think so.

3990. And that more may be reasonably expected to follow?—Yes.

3991. Is it your opinion also that the same remarks hold good with regard to pathological investigation?—Yes, I hold that opinion very strongly indeed. In a lecture which I delivered yesterday to the Veterinary College, I pointed out prominently that I thought pathological anatomy—the mere description of diseased organs, their form, and size, and colour, and so on,—has been done so frequently that little more is to be gained in that way; that it teaches little regarding the origin of diseases; and that investigations into pathology conducted on the experimental method are likely to produce very great results.

3992. Both in the prevention of diseases and in a knowledge of the true nature of diseases?—Yes.

3993. And consequently, in all probability, in the cure of those diseases?—Yes.

3994. We may take it, I suppose, that the more we know of the true nature of a disease, the more likely we shall be able to cure it?—Yes.

3995. And with regard to physiological investigations of a purely scientific character, am I right also in thinking that you are of opinion that those investigations are sometimes productive of direct practical benefit, although at the time of their performance no direct practical application may have been anticipated by the experimentor?—I quite think so. As an example of that, you may take many of those researches into the physiology of the nervous system. Those investigations into the physiology of vision have received a great deal of attention from psychologists, because it is the first attempt to trace the direct action of an external agency upon a sensory organ, and the influence carried to the brain.

3996. The Physiological School of Edinburgh has always been an extremely active one?—It has.

3997. I suppose I may fairly say that it has been the most active in Great Britain as a whole?—Yes, as a whole; recently Dr. Burdon-Sanderson has been carrying on a very large number of investigations with the aid of many able coadjutors.

3998. And yet, in the centre of so much physiological activity, you think that physiological experiments, at all events that vivisections are not carried on out of the physiological laboratory to any extent?—That is my opinion.

3999. And the students are not encouraged by their teachers to practise in their own rooms or out of the laboratory?—Certainly not.

4000. (*Mr. Hutton.*) Were you associated with Dr. Hughes Bennett in the experiments that were made, which have been recently revised by Professor Rutherford?—No, I was not, except on one or two final experiments. I think I performed only one, perhaps two experiments in connection with that enquiry, and they were not of the same nature exactly as the previous experiments.

4001. And can you tell me how those experiments were performed; they were on dogs, I believe?—Yes. They were as to the action of mercury on the liver.

4002. Were they performed under anæsthetics or not?—I really cannot say. I do not remember what was said in the report; I should fancy the dog would be anæsthetised during the time that the fistulous opening was made.

4003. Have you read the account of Professor Rutherford's own experiments published in the last Medical Journal?—No, I have not carefully read it;

J. G. M'Kendrick, M.D.

28 Oct. 1875.

I heard him give an account of them at the British Medical Association Meeting.

4004. You are aware that the dogs that were experimented on were only put under curari, and that then the effect of the various drugs upon them was tried?—Yes.

4005. What would be your impression of the amount of pain inflicted by that class of experiments? —My impression is that the animals would suffer a considerable amount of pain.

4006. And do you think, allowing, as you suggested should be done, for the effects of the anæsthetic by separate observations, that those experiments might have been done with equal scientific results under anæsthetics?—I am not prepared to answer that. Professor Rutherford has directed special attention to that subject, and has had more experience in it perhaps than anyone in Europe; and I really would not take it upon me to say that the same accurate results would have been obtained if the animal in these instances had been under the influence of an anæsthetic.

4007. But do not you suppose that curari itself might vitiate the result, almost as much as the anæsthetic?—I recollect that Dr. Rutherford pointed out that he had first tried the influence of curari alone upon the secretion of bile, and then, as I understood him, he made an allowance in his further experiments for its influence.

4008. Why should not that experiment have succeeded as well if it had been an anæsthetic instead of curari?—That is what I cannot answer, because I do not know how an anæsthetic exactly would affect the secretion of bile; that was for Professor Rutherford to investigate.

4009. I was struck with the expression which you used that you would not answer for your brother physiologists. I conclude that meant that there is a very considerable variety of opinion amongst physiologists as to the amount of pain which it is allowable to inflict for scientific purposes?—Yes, there is a considerable latitude of opinion.

4010. Now with respect to any kind of restrictive measure, do you not conceive that any man ought to be a competent physiologist who is allowed to make these experiments at all?—At all events he should be under the guidance of some one connected with physiological work.

4011. Supposing there were any psychologist making these experiments without any thorough physiological education, would you object to his being restrained?—If I heard of any one personally performing experiments of that kind, and I thought he was not a sufficiently competent person, I think I would try to point out to him that he should not do it; but I am afraid that any stringent legislative restriction would have the effect of rather preventing the advancement of physiological science in this country.

4012. (*Lord Winmarleigh.*) Would you say including the issue of a license?—I do not object to the issue of a license to persons.

4013. (*Mr. Hutton.*) But even supposing a certain amount of research was prevented in that way, would you not say it was more than compensated by the protection given to animals by such a restriction?—If I thought there was a great abuse of the power of vivisection in the country, I would take that view, but I do not think there is.

4014. (*Lord Winmarleigh.*) You do not dread its creeping in from abroad?—I do not think so. My own impression is, that this investigation by this Commission will have a most beneficial effect, apart from legislative interference at all.

4015. (*Mr. Hutton.*) You said that you would not have made some of the experiments on the eye except under anæsthetics; I suppose you meant, it being in your power to make them under anæsthetics; you did not mean that you would have sacrificed the result altogether rather than give the pain that would have been involved in making those experiments without anæsthetics?—If we had found, for example, that there was no effect of light upon the retina in a deeply anæsthetised animal, we should have tried one experiment to see the effect upon an animal without its having received an anæsthetic; but we found the effect at once. We saw there was no necessity for doing it otherwise. These experiments, indeed, were of such a character that they could not have been done *without* anæsthetics.

4016. But supposing that had been the case, and you had found that it gave great agony to the animal, should you have desisted altogether, or thought it your duty to go on?—I think I should have felt it my duty to go on. I should have done it once, and done it with every precaution possible; but really that case is very rare.

4017. I suppose you can hardly say it rarely happens; probably in these experiments of Professor Rutherford's very great pain has been inflicted?—Yes, I fancy so.

4018. So that really it is a balance of the one good result, of the scientific result, against the bad result of the pain to the animal, after all, is it not?—No doubt the two aspects are to be taken into account.

4019. I take it that your general opinion is of the strongest kind, that any practical measure which should not severely restrict research, and which should ensure humanity, ought to be adopted, if such should seem necessary? — That would depend upon the character of the measure. I do not see any objection, as I have said, to a licence granted to competent persons to enter upon investigations of this kind, something in the same way as a licence granted for anatomical work, although certainly the two cases are not exactly similar.

4020. (*Chairman.*) Your connexion with veterinary practice will enable you to tell me whether you think that the general advance of physiological science will tend to mitigate sufferings in horses, for example, and the animals which are now attended by veterinary surgeons?—I have no doubt it will.

4021. Therefore if the course of practice pursued tends to elevate altogether the scientific knowledge of the country, it will on the whole greatly diminish the sufferings of animals?—No doubt of it. I pointed that out in a lecture yesterday.

The witness withdrew.

Adjourned to Saturday next, at 12 o'clock.

Saturday, 30th October 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

G. Hoggan, M.B.

30 Oct. 1875.

GEORGE HOGGAN, M.B., recalled, and further examined.

4022. (*Mr. Huxley.*) I think you stated that Dr. Handyside advised you to conduct this experimental inquiry because you had stated to him that you had new views upon respiration?—I had done so during two medical years, and I constantly had the same advice from Dr. Handyside.

4023. Did the testing of these new views of yours require experiments upon living animals?—Whenever I had a discussion with any medical person on this question, when they could no longer contradict the views I held, they always said, "I will believe that "when you show me it on animals, and if you wish "this to be accepted by the profession you must have "it attested by experiments on animals;" that was the motive always given.

4024. Will you be so kind as to tell me what was the nature of the experiment suggested?—With regard to the action especially of the diaphragm, and the action of the intercostals. In fact, my theory did away with the necessity of muscles of inspiration. I denied the action of them as they stood, and I said that the motions of the others would be different if they acted as they were supposed to act.

4025. Then the persons with whom you discussed this matter said that that was a question which could only be decided, in their judgment, by experiments upon living animals?—Yes.

4026. Was the question ever raised as to whether such experiments could be made under anæsthetics or not?—I dare say that it has been said to me, though I could not say now who said it, but in reply to my objection that I would not give animals useless pain in proving what everybody seemed to prove beforehand, whatever their views were, the answer was sometimes made to me, "If you do not want to "give animals pain, cannot you give them anæs-"thetics?"

4027. It is a matter of fact, is it not, that the respiratory movements go on perfectly well in an anæsthetised animal?—I am not prepared to say that they do go on the same under anæsthetics as without them.

4028. They go on in such a manner, however, that all the great classes of respiratory actions are performed as they would be in the normal state, is it not so?—No; I am not prepared to assent to that proposition. We find that a little thing alters the conditions; an individual standing up or lying down alters, to a certain extent, the movements of respiration.

4029. But the problem which you propounded is one which relates, from what you just told us, to the action of one of the principal of those muscles which are commonly regarded as respiratory?—Yes.

4030. And one the action of which I think you would admit, if you had examined anæsthetised animals, was not seriously interfered with during anæsthesia?—I quite agree that it is not seriously interfered with, and I was quite prepared, and did begin to do the experiment with anæsthetics.

4031. So that, in point of fact, the recommendation to you to make these experimetns did not involve a accommendation that you should make experiments which, while they lasted, were painful to the animal?—I can say this, that the question of trying experiments on animals was put clearly to me by itself, without any consideration of anæsthetics at all; and it was only when I gave my objection to torture animals, as I considered uselessly, that it was said to me by way of overcoming my scruples, "But cannot you do it "under chloroform?"

4032. I only want to get out the facts clearly; and its results, from what you have stated, that the recommendation made to you, although there may have been no explicit statement about anæsthetics one way or the other, to perform these experiments did not necessarily imply that you were to perform experiments of a painful character?—There was the implication that the experiments were of a painful character, or I would not have given the answer that I did.

4033. But if the animal had been anæsthetised while they were being performed, the pain would have been removed, would it not?—Yes, if thoroughly anæsthetised.

4034. I think on the last occasion when you were here you brought forward as an example of an excessively cruel experiment one which is described in a work by Claude Bernard?—I did.

4035. Have you the details of that experiment here?—I have not the book with me, as I brought it down last time, and thought we had done with it; but I shall be happy to give it exactly.

4036. I think I can describe it to you sufficiently accurately for the purpose now. This experiment referred to the changes which take place in the blood in passing through a gland, did it not?—Yes.

4037. And it was further intended to show the influence of the irritation through a particular nerve, the chorda tympani upon the blood passing through the glands?—It was intended to show its action in causing the vessels to dilate.

4038. Now I think during that experiment the chorda tympani was laid bare?—Yes.

4039. And you will grant it once that that is a moderately severe operation?—Yes.

4040. And in the second place the chorda tympani was irritated by galvanic means, was it not?—Yes, generally it was tied and drawn out.

4041. Do you think that the irritation of the chorda tympani by galvanism is an excessively painful thing?—I should say that it was.

4042. Do you think that there is any evidence that the chorda tympani is a sensory nerve at all?—It is called a motor nerve as coming from the facial, but at the same time all motor nerves are found to have a large amount of sensation, reflex it is true it may be called, but still causing a great deal of pain when manipulated.

4043. But is it not a matter of fact that in looking up any work of authority on the subject, the chorda tympani would be spoken of with extreme doubt as a sensory nerve, if not its sensibility denied altogether?—Some may do so, but the professor to whom we allude is very distinct in his opinions as to motor nerves not being destitute of sensation.

4044. Has it not been made out as one of the most remarkable discoveries that have taken place in recent years, that the effect of the irritation of the chorda tympani is direct upon the secretory power of the glands? You are doubless acquainted with Ludwig's experiments?—Certainly, to irritate the chorda tympani causes an increase of secretion.

4045. Now the nerve having been discovered to have that very definite and very remarkable function, it might probably tend to increase any doubt that exists in your mind as to whether it is a sensory nerve at all ?—I believe that it is a motor nerve; but that motor nerves have pain just as other structures may have pain in which sensory nerves run; that is, the sensory nerves may be in some way connected with it. Whether the sensation is reflex or not I cannot say, but I would consider that galvanizing the chorda tympani, like galvanizing the anterior roots of the spinal nerves would cause a certain amount of pain.

4046. But you do not think it would cause more pain than galvanizing the anterior roots of the spinal nerve. You have no particular reason for thinking so ?—I have no particular reason to think so. It is a subject on which there can be many opinions.

4047. Then did I rightly understand you to say that this operation could not be carried out under the influence of any anæsthetic ?—No; at least if you understood me to say so, you have misunderstood me. I spoke of the operation, but I did not limit the operation to an irritation of the chorda tympani nerve by any means.

4048. I wish to get at this, whether this is an experiment that can be performed under the influence of anæsthetics or not; we are now speaking of anæsthetics of any kind ?—I have never seen it performed under anæsthetics. Opium would probably act prejudicially, and I cannot speak for chloroform. I have never seen the thing proved; and it is very possible that anæsthetics would have a bad action upon the secretory power of the glands; that is to say, that they would slightly alter the condition in some way or other.

4049. You have never seen Ludwig's experiment, for example, performed on an animal under the influence of opium ?—No, I have never seen it.

4050. Now, taking this experiment altogether, do you put it forward as one of the most terrible and cruel which you wish to bring before us ?—Not one of the most terrible and cruel, but a cruel experiment, and more especially cruel when performed by way of acquiring facilities in operating; as I have seen it done several times.

4051. Suppose the experiment were performed, as it was originally performed, for the purpose of determining two most important points of physiology, would you then think it an experiment to be condemned ?—No, it is a most valuable experiment, but, once proved, to repeat it is criminal I consider.

4052. I think I understood you to speak of the establishment of a biliary fistula as a very cruel experiment ?—I mentioned such as a cruel experiment performed under curari.

4053. Only under the condition of being performed under curari ?—It would not be a cruel experiment under anæsthetics thoroughly applied.

4054. I presume you have seen animals in which an experiment of that kind has been performed a few days after the operation ?—I never paid any particular attention to them.

4055. When the canula was in the duct ?—I never paid particular attention to that.

4056. You cannot tell us then, whether under these circumstances, the animal seemed perfectly comfortable and devoid of pain, or not ?—As a mere opinion, I would not suppose for a minute that it was destitute of pain. I have seen animals in all stages remaining after operations, and I was never in the slightest doubt, nor any one about me, but what they were suffering pain, although they were not continually giving evidence of it.

4057. Do you think it possible then that a dog on which that operation had been performed should, within 48 hours (as an outside limit) after the operation, run about, exhibit all its ordinary signs of health, feed with freedom, and in fact exhibit no signs of any remarkable disturbance ?—Yes.

4058. And during this time, as is necessary for the performance of the experiment, the canula is in ?—The canula is in; but if you will kindly permit me to notice, you are going on to another experiment different from the one that I spoke of. I spoke of an operation that lasted six, seven, or eight hours, a temporary operation—that is, there was no attempt at healing up the fistula. You are speaking of permanent fistula, if I understand you correctly.

4059. I have asked you those questions because I understood you to say that a canula placed within the gall duct must give rise to the same kind of intense agony as we very well know is caused in the human being by the passage of gall stones along the bile duct ?—I said I was not aware that any human being had any experience of the pain caused in tying the gall duct; all that they had experience of was in cases where gall stones pass down the bile duct, in which cases they describe the pain as being intense. And I say from their account we can form an opinion what would be the dissecting out of the bile duct from the structures with which it is included in the ligaments, cutting out and bringing it outside. It would be a most painful operation.

4060. I assume with you that the agony caused by the passage of gall stones down the bile duct is of the most acute possible character in the human subject; but then I take it if a dog with a canula in its bile duct exhibits no such manifestations of pain, shows not even any signs of inconvenience, it cannot be that the presence of that canula can give rise to pain in any respect comparable with that which is produced by the passage of a gall stone along the human bile duct ?—I am of opinion that the pain in the operation which I refer to would be much more intense than a gall stone passing along the bile duct in the human subject; but that pain (following up what I think is the intention of your question) would certainly get deadened as time passed.

4061. So that it does not follow, from the fact of a dog having a canula in its bile duct or gall duct, that it necessarily suffers the same sort of pain as we suffer when a biliary calculus passes along the same passage ?—During the acute stage, if I may use that word, I am of opinion that the suffering of a dog, in the experiment referred to, that is under curari for six or eight hours after the first making of the hole in the abdomen, would be more intense than in the case of a human being. I give that as my opinion. I may be right or wrong.

4062. I understand that you have no objection whatever to experiments for the sake of investigation, if carried out under what you consider to be proper precautions and restrictions ?—That is as near as possible my answer.

4063. You do not admit the principle which is urged by some, that experimental investigation ought to be put down at all costs and hazards whatever ?—I certainly do not. I do not wish to see it put down, if sufficient restriction would be accepted by physiologists for the prevention of abuses. But if there be a strong objection on the part of physiologists to allow any restrictions to be laid upon them, then I would take total abolition as the next best thing. But in the present condition of things I would not ask for total abolition.

4064. I understand you then to say that if physiologists object to restriction of any kind, then you would like to stop them altogether ?—That would be next best thing.

4065. But if they do not object to restriction, then you would be content with such restrictions as you have suggested ?—Yes.

4066. I understand that you think that all such experiments should be conducted in a hall with a gallery, to which the public might be admitted ?—Yes.

4067. The public being restricted, as I gather from you, to some five or ten students, and possibly as many persons who might be nominated and admitted by tickets ?—Yes.

4068. Now, leaving the students aside, what sort of people do you think it would be advisable to admit by ticket ?—Any respectable person above a certain age. I gave the idea of the British Museum reading-room ticket, as explaining what I meant.

4069. You would allow to enter into this laboratory

G. Hoggan,
M.B.

30 Oct. 1875.

G. Hoggan, M.B.

30 Oct. 1875.

any such persons as are ordinarily admitted to the British Museum?—Yes.

4070. Persons entirely without knowledge of physiology, and without any preliminary training?—Yes.

4071. Do you think that persons of that kind are competent to form a judgment as to the value, to take one point first, the scientific value, of the experiments performed?—It is possible. What I mean is, that they might be so or they might not. Very probably they would have an exaggerated idea, because I find an exaggerated idea of the importance of such experiments to be much more common than the opposite.

4072. We have had before us a very grave statement, made on the authority of a public body, respecting certain experiments, and the allegations made respecting these experiments have been contradicted very decidedly on further inquiry. Now do you not think that that sort of evil (for I think it is one), would be likely to arise very extensively if persons under no such restraint, for whom there was no such guarantee, were admitted to a laboratory of this kind?—On the contrary I think that it would have the opposite effect. There is a public body (if you have not used the name I presume I must not use it), who are speaking at present of vivisectors as if they were flourishing knives and red-hot irons over their victims. I do not believe in anything of that sort; and I believe if those same people had an opportunity of going into that gallery and seeing what was done, those erroneous impressions would be removed.

4073. So that in fact, on the whole, your purpose in suggesting this regulation is to prevent misrepresentation?—To prevent misrepresentation either of one side or the other.

4074. Now as regards the bearing of the presence of an audience of that kind upon investigation, I do not suppose that most investigators care much about publicity, because they publish the results of their investigations; but many a man would feel a certain uneasiness at being looked over and inspected if he were carrying on any form of inquiry in chemistry, we will say, would he not?—Yes.

4075. I mean to say, if you were to propose to the superintendent of a chemical laboratory to admit the public into a gallery which ran round it, I suppose he might very reasonably object on account of the distraction and the impossibility of carrying on work under those circumstances?—He might very reasonably object, seeing that he has only inert bodies to practice upon; and he assumes a right over them that we do not grant men to have over sentient animals.

4076. My use of the word "reasonable" there referred merely to its being reasonable to expect that he would be disturbed by that?—I am quite of your opinion that there would be an objection on the part of vivisectors to be over-looked.

4077. And that that objection on the ground I have stated would not be altogether unreasonable. I do not mean to ask you whether there are other considerations which outweigh that?—I do not think it is reasonable, looking at the whole thing in a just manner.

4078. That is to say that you think that the advantage which might result by the prevention of carelessness or useless cruelty would outweigh the disadvantage to the investigator?—It would.

4079. It never occurred to you to suggest, did it, that some similar regulation should be carried out in the operating theatres of the great hospitals and medical schools?—No, because the people operated upon are operated upon by consent.

4080. We have heard it stated that in some places, some countries, which shall be nameless, the surgeons are far more careless about their patients, far less gentle than English surgeons are; and supposing that their example was to be followed in England you would not think of suggesting that there should be any inspection for them, I apprehend?—I am not prepared to say that; I consider that there are many abuses even in hospitals, where tuition of students is sometimes placed before the feelings of the people operated upon, and in exceptional circumstances, such as those, what you have referred to might be advisable.

4081. You would be prepared, would you, to extend a system of that kind, in case of need being shown, to our great hospitals and theatres of operation?—In case of need being shown, certainly.

4082. I understand you to say that you would not propose to give a license to persons for physiological experimentation?—I did say so. I meant by that, that if a license was to be looked upon as a restriction, without being a protection to animals, that should be laid aside.

4083. (*Mr. Erichsen.*) I think I understood you in the early part of your examination to say that this proposal of having a public theatre or area for the display of experiments upon living animals did not emanate solely from yourself, but that it embodied the opinions of a number of persons who are interested in this question?—I did say so.

4084. Would you confine the operations in such an institution as this solely to experiments on living animals, or would you extend them to the general work that goes on in a pathological laboratory?—Simply in connexion with live animals; it would have no reference to dead matter; they might bring it there, but the place was specially to be adapted for living animals.

4085. Not for the general work of a pathological laboratory, the major part of which does not consist in experiments on live animals?—As far as I understand you you mean the examination of the organs of diseased persons and so on.

4086. Yes, or histological observations, or physico-chemical observations, being carried on there?—No, it was not intended for those purposes, though there would be no objection to have them there.

4087. If it were so intended would not exactly the same objection hold good with regard to that as would hold good as to the proceedings of a chemical laboratory being under general supervision?—With regard to pathological or physico-chemical experiments, if experiments upon animals were not in the question, then there would be no necessity for having them in a public place at all. I am quite conscious of the awkwardness of the arrangement, if I may so speak, but I looked upon it in this way, that just as the citizens of a country each give up a certain amount of personal liberty and personal pleasure for the benefit of the whole, in the same way physiologists ought to give up a little bit of their personal liberty to mangle as much as they choose, for the purpose of having cruelty and abuses corrected in general, and the animals themselves protected.

4088. This proposal, as I understand, does not emanate from you alone, but is the embodiment of the expression of opinion of a considerable number of people, as I understand you?—Yes.

4089. Then there was another point that struck me in regard to your evidence in thinking over the working of this scheme. Might not a public, uneducated in physiological research and observation as the majority would be, mistake reflex movements in a dead animal for voluntary movements indicative of pain in an animal that they might still believe to be alive?—It is quite possible.

4090. We were told the other day by Dr. Anthony that after a knacker had killed a horse, even though that horse's head were cut off, if he proceeded an hour or two afterwards to flay that animal, the reflex movements were so powerful that they might break the knacker's arm unless special precautions were taken. Now if the public in such a gallery were to see a great animal like a horse kicking so violently, might they not think that that animal was suffering intense agony, even though it was actually dead?—Well, I am not prepared to admit the truth of this, at least I do not understand the grounds of the experiment which gave such results.

4091. Dr. Anthony mentioned it as a fact that

G. Hoggan, M.B.

30 Oct. 1875.

he himself had witnessed ?—I have not seen it; but it is possible that the public might witness conditions which they thought were most painful when they were nothing of the kind, just as it is probable and possible that they would see no movement at all when most intense suffering was being inflicted.

4092. But supposing that the public saw what they supposed to be evidences of intense suffering when the animal was absolutely dead, would there not be some fear of public disapprobation manifesting itself, perhaps in hissing, or in appeals to the experimentor, who was supposed to be outraging public feeling, and who was supposed to be inflicting horrible cruelty upon an animal that was known to him to be entirely beyond the reach of suffering, but that was still supposed by this public in the gallery to be a sentient creature ?—The proposal of the gallery itself removed the chance of all active interference with the operator, such as we have heard of in the Norwich Commission. The scheme proposed that a complaint might be made to the superintendent for interference if the case was considered grave by the public; the case could be made out, and if it failed there would be a warning against people interfering again. If it were justified it would be a justification of the complaint.

4093. But would it not embarrass the experimentor very much to have a series of groundless complaints made against him which he had to answer day by day. Such a thing might very possibly arise under the circumstances that I mentioned. I am speaking of reflex movements that appear to indicate pain in an animal that is dead, that is utterly incapable of sensation ?—The thing would happen now and then, as such things happen every day in every walk of life, but it would bring its own cure, and might be provided for afterwards. I should not expect that such a scheme was to be considered as correct as a commencement, but it would be a point from which to start, and to make improvements.

4094. You would not be afraid of any outward signs of disapprobation or repugnance, manifestations such as take place in popular assemblies when they are displeased at any thing that is going on before them ?—No; the thing might happen as I say at times, but we should find that many of those who appear most excited, and most ready to exaggerate would never go there. It is within my personal knowledge that many of the people who now talk so much against vivisection retain in their possession papers in which experiments are detailed, and they dare not look into them. If they could not look into a book I do not think that such sensitive individuals would go and place themselves in a gallery.

4095. But there might be individuals of a ruder nature, and less sensibility, and perhaps more likely to make outward manifestations ?—The arrangements of the place would not, I presume, allow people to behave as they chose. In the British Museum it is possible that any one could make a demonstration, but the regulations of the place I think would provide that it should not be repeated.

4096. Then there was another proposition that you made in connexion with this scheme, and it was this, that pathological experiments upon animals should be performed there, and that the animals should be open to the inspection of the public after the performance of these experiments ?—That they should be kept in places open to their inspection.

4097. Do not you think that that would entirely vitiate the experiment, that with regard to an experiment made for instance upon the inoculation of sheep pox, or any of these experiments that have been made under government supervision or direction in this country, the result must be entirely vitiated by the public going to visit these animals whilst in a state of disease?—By no means whatever.

4098. That they would disturb the animal, irritate it and frighten it ?—No.

4099. The sympathy exercised by the public towards a diseased animal might modify the results of the experiment, might it not ?—No; though I said that they should be kept in places where the public could see them, I did not mean places where the public could get hold of them or manipulate them.

4100. As this scheme emanates from a body of individuals, and not from a single individual, I was anxious to form some notion, if possible, in my own mind as to the working of this scheme if it were recommended ?—May I be allowed to make a correction. I wish to say that I have not obtained permission from any one to bring in their names in connexion with the scheme I have put forward. I had no authority when I made that statement, and I had not expected the question to be asked me. I drafted that out, and it has been submitted to many. I will only add that I am not authorised to give any names besides my own.

4101. I would ask you if you are acquainted in any way personally with the working of any physiological laboratory in London ?—I am not.

4102. You have never worked in any ?—I have never worked in any except my own.

4103. But I mean in any public laboratories in London. You know nothing of them from personal observation, or from having worked there ?—No.

4104. (*Mr. Hutton.*) I think this is a matter of the very greatest importance, and therefore I want to have a very explicit answer. I understood you to say that in Edinburgh the students are accustomed to make experiments of these kinds so often, or at least to propose them, that the public feeling among the class of students in Edinburgh would in no way prevent men who had not got their degree, who were not properly educated medical men, making this class of experiments ?—I should say it would not.

4105. By your own experience you could testify that that state of feeling did prevail amongst a large class of students in Edinburgh ?—It was felt that if anything could be proved or bettered by an experiment the experiment should be performed without any more ado.

4106. And that by students ?—That by students, certainly.

4107. Now you have expressed in letters that have appeared in the public press the opinion that anæsthetics on the whole have been rather curses than benefits to animals ?—I have.

4108. Will you give me the grounds of that opinion, as briefly as you can ?—Principally because, as I have explained in those letters (which I have put in before the Commission), the public have generally supposed that anæsthetics were used, and they did not feel called upon to make any demonstration to save animals from pain, and while the animals were suffering pain all the time the public really thought that nothing of the kind was going on, and consequently anæsthetics had served more to lull the public than the animals. Those are nearly my words. And the reasons given why anæsthetics were not so much used as they were supposed to be, were first, that anæsthetics if given to animals in many cases bring about a fatal result before the experiment can be concluded,—if given thoroughly, that is to say; in the second place, that anæsthetics cannot very well be given unless a special assistant is there for the purpose; and that these two things together cause so much annoyance to the experimentor that he does not take the trouble of thoroughly anæsthetising the animals. This leaves out of sight that great class of experiments where anæsthetics would interfere with the true result of the experiment; and these are very numerous.

4109. Now can you give us an example of what you would call the most painful class of experiments made without anæsthetics, and necessarily made without anæsthetics, from any authorised and written record. I have had a paper given me to-day in which an experiment is described which is made by M. Paul Bert (I think it is one that has been referred to before), a very eminent scientific man in Paris, who I see has just received a prize of 20,000 francs for some scientific inquiry; and if this be an authentic account of the experiment, I think it would be very material for

G. Hoggan, M.B.

30 Oct. 1875.

the Commission to hear the general features of it?—I have also that account.

4110. (*Chairman.*) Is it from a published medical journal?—It is from a published medical work; it is a translation of Paul Bert's observations on a curarised dog, translated from "Archives de Physiologie," Volume II. of 1869, page 650. I may say that I myself have assisted at experiments somewhat similar to this.

4111. Have you got the French here?—Yes* (*producing it, and handing it to Mr. Huxley*). The translation is as follows:—"Under the skin of a "middle-sized, vigorous dog, six centigrammes of "curare in the solid state were inserted, and six "centigrammes of the same substance dissolved in "six grammes of water, were also injected. A few "minutes afterwards the animal staggered on its fore-"paws, walking on the tips of the toes; he then fell, "and presented all the signs of poisoning by curare; "he defecated, urinated, gave out a large quantity "of viscid saliva, and wept very much (*pleurait* "*abondamment*). I then opened the windpipe, and "inserted the nozzle of a bellows, to which an inter-"mittent movement was given by a machine worked "by water. (The machine fitted by M. Gréhant "in the laboratory of M. Claude Bernard at the "Collège of France). In this way an artificial "respiration of a very regular kind was kept up. "The pneumo-gastric nerve of the right side was "then laid bare and tied, and the same was done "with the sciatic nerve of the same side. After "some minutes the sciatic nerve could no longer "make the muscles contract. During ten hours the "action of the nerves and the condition of the pupils "were examined from hour to hour, and the following "facts ascertained, which it will be sufficient to state "once for all. The pupil of the right side was con-"tracted, that of the left side much dilated. The "galvanisation of the pneumo-gastric and sympathetic "of either side in the neck caused dilatation of the "pupil and protrusion of the eyeball. This effect was "most marked on the right side, but real also on the "left side. The galvanisation of the pneumogastric "nerve of either side completely arrested the action of "the heart. The iris of the healthy side (left side) "became contracted when light was allowed to fall upon "it. Moreover, and this is the point to which I par-"ticularly wish to call attention, galvanic excitation "of the central end of the tied sciatic nerve, of the "same in the median nerve, and of the same in "the infra-orbital nerve, caused a contraction of the "bladder, which (the sphincter of the urethra being "paralysed) made itself evident by the emission of a "small quantity of urine. This effect can only have "been obtained through the intervention of the "sensory nerves of animal life. Neither the pneumo-"gastric nor the sympathetic nerves in the neck, nor "the splanchnic nerves, gave any such result. After "ten hours of artificial respiration, the animal became "three or four degrees colder (temperature of the air "12°). Next morning it was dead, although the "artificial respiration machine still worked; perhaps "during the night there might have been some "irregularity. The urine found in the bladder, as "well as that previously collected, contained a great "deal of sugar. The viscid saliva, secreted in great "abundance, gave a slight but manifest yellow pre-"cipitate with the blue test fluid. This is the first "time, I believe, that sugar has been found in the "saliva in the course of induced diabetes. But let us "return to the action of the sensory nerves on the "contraction of the bladder. This result is interesting "in itself, since it explains certain known relations "between the bladder and the sensory nerves; such as "the desire to urinate which follows the sharp sensa-"tion of external cold on entering a cold bath, or a "very hot one. Moreover, in following out this "question, it will be possible to solve certain very in-"teresting physiological questions. On the one hand, "the intra-medullary origin and the place of exit "of the motor nerves of the bladder might be easily "be determined. We shall then discover by what "channel those centripetal disorders come; for ex-"ample, from the infra-orbital nerve passing along "the whole length of the spinal cord; if they belong "exclusively to the white columns, or if they spread "into the grey substance. The experiments of "Budge and Schiff might be thus usefully rendered "complete. However, this may be, here is a dog "under curare, upon whom, during ten hours, the "action of the pneumo-gastric and sympathetic "nerves remains intact; whether these be excited "directly by electricity or put in action by their natural excitor, that is, reflex action." I have written the following observations of my own:—"Remarks "on the above in plain English. In this experiment "a dog was first rendered helpless and incapable of "any movement, even of breathing, which function "was performed by a machine blowing through a "hole in its wind-pipe. All this time, however, 'its "'intelligence, its sensitiveness, and its will, re-"'mained intact; a condition accompanied by the "'most atrocious sufferings that the imagination "'of man can conceive' (*vide* Claude Bernard, in "Revue des Deux Mondes, 1st September 1864, "pp. 173, 182, 183, &c.) In this condition the side "of the face, the side of the neck, the side of the "fore-leg, the interior of the belly and the hip, were "dissected out, in order to lay bare respectively the "sciatic, the splanchnics, the median, the pneumo-"gastric and sympathetic, and the infra-orbital "nerves. These were excited by electricity for ten "consecutive hours; during which time the animal "must have suffered unutterable torment, unrelieved "even by a cry. The crowning discovery made, to "which the experimentor calls special attention, "being that, at times, when thus tortured, *it* "*urinated!* The inquisitors then left for their "homes, leaving the tortured victim alone with the "clanking engine working upon it, till death came "in the silence of the night, and set the sufferer free."

4112. (*Mr. Hutton.*) Have not you a little exaggerated the effect by stating that "these were excited by electricity ten consecutive hours." You meant to say with intervals; that the sufferings went on for ten consecutive hours, but not the sufferings as increased by electricity?—It was tried every hour during that time; but as there were a great number of nerves to excite and get at, it would probably be a consecutive operation throughout.

4113. You do not mean that the electricity was going on during the whole time exciting the sensitive nerves?—No; two nerves would not be excited at the time; after one was excited they would go to another.

4114. The French phrase is *pendant dix heures on examine d'heure en heure,*" that is to say, that hour after hour they were examined?—Yes, but in the interval some other nerve was being tried.

4115. Now your attention has been called very much, has it not, to the action of curari?—Very much; and I believe I was the first who, in this country, brought up the question of its abuse.

4116. You do not believe it to be an anæsthetic in any degree whatever, do you?—I am as positive on that point as I am on any point of physiology; and I have any amount of material to prove it from the best physiologists in the world.

4117. Did I rightly understand you to say that Claude Bernard's opinion is, that, so far from being an anæsthetic, it rather increases the sufferings of the creatures to which it is given?—I have no documentary evidence to state exactly the amount, but I can say that he expresses himself as if it was something horrible beyond all conception to be under curari.

4118. (*Mr. Forster.*) Where does he say that?—I have got the book here (*handing it in*), the *Revue des Deux Mondes* of the 1st of September 1864.

4119. (*Mr. Hutton.*) Can you put in any cases in which the effect on man has been described minutely?—I can. I have a translation here of the most im-

---

* Appendix III., § 4.

G. Hoggan, M.B.

30 Oct. 1875.

portant parts from that article, to which I have just alluded; it is a classic article on the subject. And I have also added some of those other experiments that you refer to. Liouville gives a very graphic description of a case where an overdose had been given to a patient, and artificial respiration had to be kept up till after he recovered. "The patient then related," says Liouville (*Bulletin Général Thérapeutique*, 1865, page 404), "all he had felt, the preservation of his in-" telligence, the annihilation of all power of movement, " of which he gave a clear account, witnessing all that " went on around him, without being able to take any " part in it, the fears freely expressed by some young " assistants present being by no means re-assuring to " him." That is one case, and Bernard also mentions at page 1117 of the *Revue Scientifique*, for 1874–5, that, " We have the accounts of individuals who had been " inoculated with curare, but to a degree which had " not stopped the motions of respiration, and conse-" quently permitted the individuals to return to life, " I mean to movement. These have then been able " to relate that during their paralysis they had never-" theless been fully conscious of their existence, and " of all the impressions which excited their senses." There is another account in the "*Revue Scientifique*," I cannot give the page, but I give the work (it is a very large work) in which he mentions that a patient had been operated upon under curari and suffered "*douleurs atroces*." I can repeat such opinions nearly word for word, from three or four of the greatest experimentors, in fact they are nearly all agreed upon it abroad.

4120. Has your attention been called to some experiments by Mr. Yule, in which he supposed that he had shown that, as regards the frog at least, curari was an anæsthetic?—It has.

4121. And what is your view of the success of those experiments?—My view of them, if I may be allowed to express it so strongly, is, that they are utterly unworthy of credit, as far as they were published in "*Nature*." I have heard reports about pinching, which do not appear in "*Nature*" at all, and which would alter the consideration of the question; but as they stand in "*Nature*," they are utterly unworthy of credit, and they are opposed in the most distinct manner to experiments of which I am prepared to read the account, performed by the greatest authorities to this subject, and that I myself have witnessed performed by them.

4122. Will you read us that?—It is said that in curari it is simply a question of pulling the animal's hind leg out, and because it does not draw it back, it is argued that it has lost volition and consciousness; and that is the point I will address myself to first, although the first three lines of the article I refer to, contain a grave mis-statement of the fact.

4123. You mean to say a grave mis-statement of the facts as you have understood them?—As all the scientific world, up to the time of the publication of my *exposé*, have understood them. Now I have here Claude Bernard's classic experiment, as it is considered, on the frog, and I am able to give the same opinion from Köllicker, it is the one, I think, that Mr. Yule refers to, and which is explained also in the work from which I have read before, as well as in the *Revue des Deux Mondes*.

4124. (*Mr. Huxley.*) I imagine you are going to read Bernard and Köllicker's evidence on which they arrived at their conclusions somewhere about 1863 or 1864, and it so happens that I experimented myself at the same time, and arrived at the same conclusions?—Principally. I have instances to give in 1875.

4125. (*Mr. Hutton.*) What is the date of this experiment?—It is a constant date. I saw it performed a year and a half ago several times.

4126. But the date of the book out of which yoy quote?—The book I quote from has this classic article in it. I will give you now the very latest published opinion on the subject that of Professor Vulpian.

4127. (*Chairman.*) It is the latest opinion of authority with which you are acquainted, I understand you?—Yes.

4128. (*Sir John Karslake.*) The latest which you recognise as an authority?—Yes.

4129. (*Chairman.*) And what is the date of it?—He states in "*Lecons sur l'appareil locomoteur*," at page 60, published in 1875, that curare does not act on the nerves of sensation. "Curare does not " act on the sensory nerves, or at least does not " abolish their function," and at page 661, "Curare " which abolishes voluntary motion in no way annuls " sensation, at least in ordinary doses." I hope it is understood that I am speaking of physiological doses for physiological experiments. In a large dose it destroys life as well as sensation.

4130. (*Mr. Hutton.*) Then it is your impression that any dose which really abolishes sensation also abolishes life?—That the one would come close on to the other; as near as has been ascertained. The action of curari follows a regular course over the body.

4131. Will you give us shortly your reasons for thinking Mr. Yule's experiments with regard to curari to be illusory?—I shall do so by pointing out that his best reason is simply this, that in a curarized frog, of which the hind legs are not curarized, on laying it down and extending out its hind leg it does not draw it up; he argues from that, I consider wrongly, that the leg being, as he considers, in an uncomfortable position, if it had consciousness and volition, it would draw it up; and because it does not draw it up from an uncomfortable position he says it has lost consciousness and volition.

4132. I want to ask you just one question as to the difference between narcotics and anæsthetics. I asked a very high scientific witness the other day whether it was true or not that narcotics only dulled pain, while anæsthetics removed it, and the answer was that it was directly contrary to the fact. Now have you any authority for saying that there is a distinct difference in kind, that narcotics only dull pain, while anæsthetics remove it?—I have given already an opinion on that point, in the words of Professor Claude Bernard.

4133 (*Chairman.*) At what date was that opinion given?—It was in 1870, "*Revue des Cours Scientifique*," volume 6, page 446:—"Morphia is not an " anæsthetic, but a narcotic (*stupéfiant*). When it has " taken effect on a dog he does not seek to escape; " he has lost the knowledge of where he is; he no " longer notices his master. Nevertheless sensibility " persists, for if we pinch the animal he moves and " cries. At the same time you see that morphia " plunges dogs into a state of immobility, which " permits us to place them on an experimenting " trough without tying or muzzling them." That gives a very good idea, and I have seen the thing done.

4134. (*Mr. Hutton.*) We have been told by some of the witnesses that by far the most painful of their experiments have been on the origin of tuberculosis, but also that they were by far the most important. Is there any difference amongst high authorities as to the importance of those experiments, as far as you know?—I have had my attention called to this in consequence of an article in the "Times" and elsewhere, and I can only say that according to the very latest information that we possess from the Continent, the experiments and the conclusions which are most relied on,—those of M. Villemin,—have been completely upset at the late Medical Congress in Brussels, by Professor Crocq. We have the whole thing in the "*Revue Scientifique*" for the 2nd of October 1875, where it appears that all the conclusions were upset, and special attention directed to the contradictory opinions now existing amongst nearly all experimentors on that subject.

4135. (*Chairman.*) Do you adduce that for the purpose of showing that no further experiments are desirable?—On the contrary, I simply bring it in to show that those experiments which were supposed to have justified all experiments on animals on this question have been upset by the very latest investigations upon the subject. Both Professor Crocq's

G. Hoggan, M.B.

30 Oct. 1875.

reasoning and a letter subsequently from M. Villemin are to be found in the last two numbers of the "*Revue Scientifique;*" the one came last week and the other the week before. M. Villemin in his letter acknowledges that he has modified his ideas, and that the whole field still lies open for work.

4136. (*Mr. Hutton.*) Do you believe that the experiments of M. Villemin have been for the same object as those of Dr. Burdon-Sanderson, or have you no knowledge on that subject?—I have no special knowledge of Dr. Burdon-Sanderson's experiments. They seem to have gone about it in different ways, one by mechanical irritation, and the other by specific inoculation.

4137. (*Mr. Huxley.*) Now as respects this discussion between M. Villemin and the Reporter of the Brussels Congress, M. Crocq, I take it the whole difference between them lies in this, that M. Villemin says that tuberculosis is a specific disease requiring a certain kind of poisonous matter for its production, whereas M. Crocq denies that proposition?—Those two things are included certainly in it.

4138. But, on the other hand, M. Crocq has not denied, but on the contrary he has considerably extended, the statements made by M. Villemin as to the different modes of treatment by which tuberculosis can be artificially induced?—Professor Crocq has contradicted the ideas of M. Villemin, that true tubercle (if we know what that really is) cannot be produced except by being inoculated in a certain way, and that it is not hereditary. That was another part of M. Villemin's theory, which he has given up apparently.

4139. Nevertheless there is a vast body of experimental evidence common to the two, which is of great value in its bearing on the ætiology of tuberculosis?—It all proves what it is *not.* Nearly all the experiments have proved what tuberculosis is not; they have only contradicted each other. I am not aware that they have come really to a better knowledge of what tubercle is than they had 30 years ago.

4140. Now, I should like to ask you a question or two about this case which you have put into our hands—Paul Bert's observations on a curarized dog. In the first place, as I read this, it is stated that the various nerves here mentioned were all tied at starting?—It only mentions that two nerves were tied at starting.

4141. At the commencement of the experiment?—That the pneumo-gastric and sympathetic and sciatic nerves were tied at starting; it was a means of lifting them up out of the dissection.

4142. Then I do not find that M. Bert himself gives any opinion at all as to whether the animal was capable of sensation or not?—He says that those effects were through the sensory nerves of animal life.

4143. But that is an entirely different statement; as for example, supposing a frog to have its head off and I irritated its foot, the frog's leg will kick, and that result will be produced because a certain impression has been conveyed through the nerves of sensory life; and I might state that with perfect consistency, though I believed that the animal did not feel?—Yes.

4144. So that M. Bert's statement to the same effect comes to nothing?—No; we are nearly all agreed that the frog gives appearances in that way, which it is not correct to reason from in the higher animals.

4145. I will go back to the case which has been brought before your notice by Mr. Erichsen. He told you, on very good authority, that a horse, for some time after death, if the knacker begins to skin it, kicks out. Now it would be perfectly proper to describe that, even though the horse's head is cut off, as an effect produced upon the nervous system, through the nerves of sensory life, would it not?—I am not sure that it would. I am not prepared to pass an opinion on that matter. First, I am not certain of the thing; I have never seen anything like it; and again, there is this, that we can get it from the muscles themselves, apart from the nerves, as far as I can understand the question.

4146. Have you never seen in the case of an animal of the degree of organization of a horse, such as a dog, that after the destruction of the cerebral hemispheres, or such injury as entirely destroys consciousness, that animal exhibits reflex action, brought about by influences carried to its nerve-centres, through the nerves of sensory life?—I cannot fix on any occasion where I would be certain of that fact. I have seen such displays, which I put down to the action of the muscles themselves. We know that the muscles can act apart from the nerve-centres.

4147. Have you ever seen a case of paraplegia?—Yes, I think I have.

4148. Under those circumstances, where the lower half of a man's body is paralysed, and he is utterly unable to feel any stimulus applied to his feet, is it not a matter of notoriety that if you tickle the soles of the feet they will be drawn up?—Yes.

4149. And does not that impression conveyed to the soles of the feet act through the sensory nerves?—I am not quite prepared to give an opinion upon that point.

4150. You are not prepared to give an opinion upon one of the fundamental facts in every book of physiology?—I might give an opinion, but so hasty an opinion on a subject that requires thinking about, and explanation, might be wrong and inadvisable.

4151. Would you allow me to speak of this as a statement made probably by every physiological teacher in the world, and which has been made for the last 30 years in every physiological book. I am not putting to you a new and exceptional case, but one familiar to everybody who has paid the least attention to physiology?—I can say that it is considered to be owing to a reflex action going up to the cord and coming back from the cord again.

4152. And going up to the cord through the sensory nerves?—That is the explanation of the thing that is given.

4153. Have you any doubt that that is a correct explanation?—Well, I must say that I always felt a certain amount of doubt about the explanation of reflex action; that is merely as an opinion. I do not mean to say that I am prepared with another theory to explain it.

4154. Of course if these elementary, what are commonly considered, truths of physiology are doubted, it is no use our discussing the question any further; but supposing that anyone thought himself justified in believing that under these circumstances a person might exhibit movement, the result of stimuli to the sensory nerves, and yet not feel them, he then might think that all these things that have taken place in this curarized dog might have taken place without sensation, supposing he had reason to believe that curari is an anæsthetic?—I do not suppose for a minute that Paul Bert considered that curari was an anæsthetic.

4155. But if he had so considered it, then he might have used the phraseology which is here used, and yet have believed that the animal was not, in the proper sense of the word, sensitive?—To acknowledge that that is possible is all that I can do; it is scarcely within the bounds of probability.

4156. That, of course, is a question of opinion?—Yes.

4157. Now as to the scientific results of this experiment; what I find is, what to me is exceedingly interesting and very remarkable, that is to say, by this experiment it is established that the extremities of all the ordinary motor nerve are absolutely paralysed, but that nevertheless under a full dose of curari those branches of the sympathetic which terminate in muscles, and those branches of the pneumo-gastric which terminate in muscles, are not affected?—I do not suppose for a minute that he proves anything of the sort. It is pretty well known that while curari produces an effect on the sciatic nerve, the same dose does not affect the pneumo-gastric nerve, but that a greater dose will certainly affect the pneumo-gastric,

G. Hoggan, M.B.

30 Oct. 1875.

and that it then fails to affect the heart when galvanized. He proves nothing of the sort there.

4158. All I am speaking of is the statement by Paul Bert which you have given us, "However this "may be, here is a dog under curari, upon whom "during ten hours the action of the pneumo-gastric "and sympathetic nerves remains intact." Now, either M. Bert was telling the truth in writing the account of his experiment, in which case his statement is accurate; or he was not, in which case you cannot build anything upon it. Do I undersand you to deny that his statement is true, that during ten hours the action of the sympathetic and pneumo-gastric nerves remained intact?—It is quite true, but to stop there would give an erroneous idea. It simply means that certain nerves are paralysed before certain other nerves, and it is certain that the sciatic is always paralysed by curari, and by a smaller dose and quicker, as a question of time, than the pneumo-gastric; the pneumo-gastric requires a much larger dose to affect it than the sciatic.

4159. Then that shows that there is something very singular about the action of curari, and something which by no means could have been imagined *à priori*. You are not acquainted with any *à priori* reason for supposing that the pneumo-gastric or sympathetic should not be affected when others are?—On the contrary that was the puzzle, why the pneumo-gastric having motor fibres should not be paralysed as quickly as the sciatic; and it was only by increasing the dose that they discovered that the curari goes step by step from one particular nerve to another, some being more sensitive than others to its influence, and that it always follows that same course; that this thing, which at first was a puzzle, has been now clearly explained by increasing the dose, explained by the comparative effects of curari over the system.

4160. But that is only an explanation of the statement, which I asked your assent to, as to whether it is not a very singular thing, and a thing not to be expected *à priori*, that curari should behave in one way in regard to the action of the pneumo-gastric, and in another way in regard to the action of the sciatic?—It is curious, but it has been proved to be true, that it has different effects.

4161. (*Mr. Forster.*) I understand that that effect had been proved before this experiment?—Yes, before that experiment; but it is a valuable thing that one point, that the pneumo-gastric should still retain its power, showing that the dose of curari was small, and we have had clear proof of what the effect of that dose was when small. It is a valuable point, as illustrating what I formerly said.

4162. (*Mr. Huxley.*) That is one point on which we have had evidence in this experiment. A second point is mentioned by M. Bert himself:—"This is "the first time, I believe, that sugar has been found "in the saliva in the course of induced diabetes." Supposing that to be true, it would be an important fact, would it not?—I am not aware that that has any particular importance about it. It is a little phenomenon and might not happen again, and it is not the one to which he calls special attention.

4163. Thirdly, supposing these experiments to be correct, they throw what to me is a very remarkable light upon the manner in which the action of the bladder is affected by the sensory nerves. I do not ask you whether you think that the experiments establish what they were supposed to do or not, but whether, supposing they do so establish them, that result is important or not?—It is a result that has been known, I think, to the most common observers of little things. That is what he himself refers to. To pinch the skin in many persons causes them to urinate. Upon causing intense pain the bladder contracted and gave forth a certain amount of urine. It is the smallness of the result compared to the immensity of the pain that causes this experiment to be so peculiar.

4164. That is your opinion; but I have indicated three several points which might very fairly be regarded, I do not say justly, but might very fairly be regarded, by M. Bert himself, as results of considerable importance. It may be that you do not think them to importance, but I do not think you will deny that it may be a fair thing for M. Bert, who made the experiment, to consider them of importance?—I did not consider M. Bert's ideas in the matter, but the ideas of the British people on reading the experiment, and whether they would like to see the same thing commonly done in England, as it certainly will be if no stop is put to such practices.

4165. I understand you to say that you have taken your own ideas of this subject, and not paid any attention to those of a person who probably, without any disrespect to you, is as competent to form a judgment on the matter as yourself?—I have translated, as nearly as possible, his own words. I have made comments upon the experiment for those who cannot understand technical language, but there is the translation for every one to compare it for himself with the original. No liberties have been taken with the translation. It is for people to consider whether it be correct.

4166. Then do you consider that the statement, "that these were excited by electricity for ten "consecutive hours"—which, I think, to most persons' minds would mean that the irritation went on for ten consecutive hours—would convey the sense of the original?—Yes. I could not suppose that people would think that there was a special battery for every separate nerve, but that as there were a number of nerves to be gone over, and from the observations which he mentions afterwards, it would take up all the time of the operator, and that all the time the animal was suffering unutterable torment.

4167. (*Mr. Hutton.*) You mean that some one nerve was always being excited?—Some nerve was being excited, or some little operation was going on.

4168. (*Mr. Huxley.*) All that we have here is evidence to show that there are five nerves which are irritated; the irritation of those five nerves, as you must be perfectly aware, from having experimented in these matters, would probably take about two or three seconds apiece?—I never saw an experimenter going in such a hurry about it, I must say.

4169. Do you think it actually needs longer, suppose we say two or three minutes apiece?—The ten hours during which it lay in this state included, of course, many things that would take away the attention from one nerve or another. For instance, laying bare the splanchnic nerve, and laying open the whole of the abdomen, and clearing out the intestines in order to find these nerves, which is very difficult, even in the dead subject. That operation was included in the 10 hours, but the unutterable torment was in no way lessened because the other nerves were dropped in order to get at the splanchnic nerve in the abdomen.

4170. You do not think that writing for the general public, and knowing the sort of feeling existing on these matters, a statement which could not possibly have been misunderstood would probably have been more useful to them?—I consider that when I put forward a statement with the translation along with it, I do all that is required to enable people to form an opinion of the thing for themselves.

4171. And you think that you have fairly stated what would in the general opinion of physiologists be the scientific value of this experiment when you say, "the crowning discovery made, to which the experi"menter calls special attention, being that at times "when thus tortured it urinated"?—I think that it is a fair mode of stating it, and that having consideration, not for Paul Bert and physiologists, but for people at large, and for animals in particular, if, as the friend of the dog, I were to express it ten times stronger with any number of curses on the head of the man who did it, I should be justified.

4172. You quote incidentally a passage from an article by M. Claude Bernard in 1864 to the effect

G. Hoggan, M.B.

30 Oct. 1875.

that "all this time its intelligence, its sensitiveness, "and its will remained intact." You did not think it necessary to state here in view of the popular feeling on the matter that although this was the view of M. Claude Bernard, and a number of other persons at that time, yet, that of late, whether rightly or wrongly, other competent persons had argued that that was not the case?—I did not think it necessary to enter into any such explanations; I gave Claude Bernard's authority, the book where it was found, the date, and everything. I give the words merely, within inverted commas.

4173. Is it not rather a serious thing when you are dealing with persons who do not know anything about a matter, and who have no access to the channels of information, when you know that there are two views of a case current on good authority, to put only one before them?—No; when the party who is most interested has not got the power to put any view, that is to say, the animal which is suffering.

4174. My question was rather whether, without reference to the animal or anything else, except the interests of common justice, it is not well to state a disputed case in such a manner as shall not lead people to believe that it is not disputed. I suppose you would agree to that general principle?—I am afraid that I would have to make an addition with regard to the motives of those who dispute it, that would not perhaps be in place here.

4175. Then I think that just now you cited Vulpian's opinion, as a recent expression of his unqualified belief that curari does not in any way act as an anæsthetic?—In ordinary doses.

4176. It turns out, from the wording of that opinion, in the first place, that Vulpian said that in his judgment it did not affect the functions of the sensory nerves. I think those were the words?—That it did not abolish their functions.

4177. And as I have just now shown (and as I understand you have assented in a general way in your answers to my questions), a man may quite well believe that the functions of the sensory nerves are not interfered with and yet may believe anything he pleases about the abolition of conciousness. So that, taking that part of M. Vulpian's opinion, it does not count either way?—The real fact is, that it is scarcely within the bounds of possibility that any man in France would suppose that curari is an anæsthetic, or has any idea of the sort. I may give that as as clear an opinion as I can; I say it is hardly within the bounds of possibility that a man could have such an idea.

4178. We seem to be driving at two points, but I am endeavouring to show, or rather to put to you this, that this recent expression of opinion by M. Vulpian, if we take the first part of it, does not properly bear the same construction as the expression of opinion by M. Claude Bernard ten years ago. All M. Vulpian says is, that he believes curari does not abolish the functions of the sensory nerves?—Yes.

4179. And in that he does not mean that it may not abolish the functions of the nerve centres?—He explains further on that it abolishes motion.

4180. The second point is that curari, in moderate doses, does not affect sensation?—In ordinary doses, he meant physiological doses; that it does not annul the function of the nerves.

4181. Will you read again your note of Vulpian's opinion?—"Curari does not act on the sensory nerves, "or at least does not abolish their function." Then, "Curari which abolishes voluntary motion, in no way "annuls sensation, at least in ordinary doses." I may couple with that, if you will allow me, that it is held by many that it vastly increases the power of sensation; only I have no documentary evidence for that. I have been told so by distinguished physiologists, but as I have not documentary evidence to give, it is well to leave it out.

4182. M. Vulpian says, that with ordinary doses it does not abolish sensation?—Yes.

4183. It is perfectly clear from his giving his opinion in those words that he leaves the question open, whether in large doses it does so or not?—Very clearly, and I would just give the same opinion as he does, that if you increase it a little bit, it destroys, not only the sensory nerves, but the whole individual.

4184. Then, did I rightly understand you to say, in reply to an inquiry by Mr. Hutton, that sensibility is not destroyed by narcotics?—Such was the opinion that I read, and I gave it as my own too, that it was not destroyed. The opinion was given that sense was dulled, the consciousness of what had been suffered; the animal did not try to run away, but sensibility still persisted, as shown by the animal crying at the moment that it was pinched.

4185. Surely we are at cross purposes; because if ever you have happened to take an overdose of opium, I presume you found your own sensibility considerably vanishing?—If any one pinched my skin, then, I think I should feel that, but half a minute afterwards I might have no remembrance of it.

4186. Would the phenomena which you would manifest be different from those which would be exhibited if you had injured your spinal cord in the neck; I mean so far as irritation of the surface is concerned, below the point of injury?—I should be quite conscious of the narcotism; I should feel the whole pain of the pinching, which I should not do in the other case.

4187. May I ask what is the evidence of that?—I read out the opinion just now of Bernard.

4188. But the evidence is what I ask for?—The evidence is very easy to find; if any one takes a dose of morphia or opium, he will feel the pain where he pinches himself, but as the remembrance of it goes away he feels almost unconsciousness of the pain he endured.

4189. Then do I rightly understand you to say that even in the deepest narcotism produced by morphia or opium there is no real insensibility to pain?—Physiologically speaking that is the opinion; Persons under morphia or opium feel the pain, but they soon forget it.

4190. Then it is simply because they forget it, you mean?—They forget the pang immediately afterwards.

4191. It is because this is so entirely new to me that I want to question you about it. Then with an excessive dose of morphia, for example, a person is nevertheless competent to feel, and does feel, any injury done to him, but forgets it directly; is that what you say?—I only speak in reference to an ordinary physiological dose of morphia. There is a certain stage in narcotism in which we cease to exist.

4192. I am speaking of a period long before ceasing to exist; I only mean when a person is in a condition of heavy narcotism?—And I am only speaking in reference to narcotism in physiological experiments; I believe that the question is turning on that point.

4193. It comes to this: let us suppose that in some cases a dog has opium administered, and when he exhibits certain signs of narcotism he is operated upon; now do I rightly understand you to say that if a human being were in a parallel condition of narcotism, he would feel all that was done to him?—He would feel it.

4194. But what is the evidence of that. I mean as apart from opinion?—The evidence is given in the paper before you. I read that the dog was narcotised; it was laid up, and the professor said, "You "see that this animal is in a state of immobility, "which allowed me to lay it up here on the experi- "menting trough; it does not seek to run away, "but whenever I pinch it you see how it cries; it "is sensible to pain, although in this semi-un- "conscious state it does not seek to run away."

4195. What you mean to say is, that there are some conditions of narcosis in which an animal is insensible to small impressions, and sensible to large ones?—I have been limiting my remarks to

G. Hoggan, M.B.

30 Oct. 1875.

the condition which is induced in experiments on animals.

4196. (*Mr. Forster.*) Looking at the account of this experiment the animal seems to have been ten hours under treatment, and then the operators left. Do you imagine that it was necessary to the success of the experiment that the animal should be left alive and not killed ?—I have seen the thing often done.

4197. But in this particular case ?—It simply meant this, that next day they could work upon it; if they kept the dog it might still have life enough in it to see whether its nerves would still act. No doubt they intended to continue their operations the next day, but death came in the interval, and thwarted them.

4198. You stated last time that you had been Demonstrator of Anatomy at Edinburgh; what does that mean, if you please ?—It means that during the day I taught the students practical anatomy, and in the evening I delivered a course of lectures on regional anatomy to the class.

4199. (*Lord Winmarleigh.*) As you do not object to all vivisection, I presume you would not object to its being still further tested on animals what is the real power of curari ?—I certainly would object to opening up a question which has been so thoroughly ascertained before, more especially to tyros beginning questions which dozens of the best physiologists in the world have laid aside as the most complete thing in physiology.

4200. (*Sir John Karslake.*) When did you cease to be connected with the anatomical school at Edinburgh ?—In 1872.

4201. How long had you been residing there, and demonstrating in that school ?—I had been demonstrating in that school for two sessions of the previous year. I had been a student in that school two years previous to that.

4202. Two years previous to 1870 ?—In 1868–9, 1869–70, 1870–71. It was in 1870–71 that I was demonstrating.

4203. Do I rightly understand that your knowledge of what was being done in Edinburgh is confined to the years from about 1867–8 to about 1872 ?—With regard to my personal knowledge of what is being done in Edinburgh at present, of course as I am fixed in London I have no personal knowledge in the way of visiting the place. But I have the knowledge, for instance, of Professor Rutherford's experiments, which have been published in a letter in the newspapers, which are altogether opposite to what occurred five years ago when such experiments were not yet introduced. Those experiments show the progress that experimental physiology is making in this country.

4204. The knowledge which you have obtained personally as to what has been going on at Edinburgh was between the years 1867 and 1872, or about that time ?—It was up to two years ago; although I was not a student, I was in Edinburgh teaching separately afterwards.

4205. Did you yourself attend any of the experiments, or the vivisections that took place in the laboratories for the benefit of classes ?—I did not. The experiments that were performed at the class there were very small things indeed, and I went to the continent for the purpose of getting a knowledge of the practice which I was unable to procure during my student life, and having obtained that, I would no longer practise it.

4206. You yourself never demonstrated upon the living animal before any class at all in Edinburgh ?—Never. I taught anatomy, not physiology

4207. Now let me ask you this question, you said, as I understood you, that medical students were in the habit of practising vivisection in private ?—I did say so.

4208. In what year was that ?—All the time that I was there.

4209. From 1867 to 1872 ?—All that time; and they often, of course, amongst each other spoke of such experiments. One would say, "I tried so and so." I took no special note of the thing at the time as to who said this, only there was the general knowledge which no one for a moment would doubt, that students when they had an opportunity, and thought that it would be advisable to make a vivisection, proceeded to do it.

4210. Then, as I understand you to say, the students who attended the lectures in the physiological laboratories were in the habit, according to your view, of practising these experiments themselves ?—It was not confined to students who attended physiological laboratories. In the University of Edinburgh practical physiology is not a compulsory class, so that all the students do not take it.

4211. I do not see that that in any way affects the question that I am putting, which is, that, according to your statement, a student or students who did attend these classes, by themselves practised such experiments upon living animals ?—We had few experiments, in fact scarcely any experiments, to attend when I was there, in any class; but the students whom I referred to were medical students, who, perhaps, never attended a physiological laboratory at all. I wish to point out that it is not a compulsory class in Edinburgh, and therefore they did not take it.

4212. Now then, the experiments which they practised according to you, were experiments which they thought necessary for illustrating some truth or other ?—No; it was considered, perhaps, enough to get an animal and open it in order to see its heart beat.

4213. Can you give the Commission anything which will enable them to ascertain when or where any particular person did perform these experiments in private ?—I cannot give the Commission any such information, and it is almost impossible for the Commission to obtain information of that sort.

4214. Can you recall to mind the name of any single person who spoke to you and stated that he was in the habit of performing these experiments ?—I can.

4215. Have you any objection to state the name ?—I would rather not state any names; it would have rather a tendency to deter witnesses from coming forward, to bring in names.

4216. Did the gentlemen who spoke to you, and whose name is in your mind now, make the least secret of what he was doing ?—He told me (I may tell his name, but it would not help the Commission in any way) that he and another student had experimented on a number of cats; I think the number he said was 15.

4217. For what purpose ?—I did not get that out of him at all. It was simply in connexion with my own theory that he said so in advising me to do it.

4218. Now can you give us the time, the year, or about the year in which it was made ?—Yes, the statement was made on the day that I read my Dissertation before the Royal Medical Society, but the gentleman who told me is dead. I can give you the precise date, I think. The date on which that young gentleman told me that was the 25th of March 1870.

4219. He told you that he and another gentleman, whose name he mentioned, made experiments on cats ?—Yes.

4220. Did he tell you for what purpose ?—I think he told me, but I cannot remember now what it was for.

4221. Did he tell you where they were made ?—Certainly, in his own rooms.

4222. Did he describe the nature of the experiments ?—I know this, that he opened up the thorax and the abdomen.

4223. Did he tell you, or had you the curiosity to ask, for any explanation of the object of his making these experiments ?—I do not think I inquired the object; he told me that he had made those experiments, and he told me what he had observed during those experiments, which might be made to bear upon my theory of respiration, which was being read and discussed that night. Every one was coming to me

G. Hoggan, M.B.

30 Oct 1875.

and saying, "Why, you ought to demonstrate this "on animals," and it was one of the students, whose name I can particularly recall at present, who told me this in connexion with himself.

4224. Have you any objection to state his name?—I have no objection, but he is dead now.

4225. Can you tell us the name of the other gentleman who was assisting him in these experiments, and whether he is living, or not?—I did not know him; it was a French name, and I did not pick it up.

4226. Is there any other instance you can give me to bear out your statement that this was a practice at Edinburgh?—I could give no particular instance.

4227. And you cannot give me the name of anybody who asserts that he has practised it in his own room, besides the gentleman whom you have mentioned?—Not at this present moment. Things of the sort have been said to me dozens of times, but I have retained no special remembrance of what was said in the matter.

4228. Then not having retained any special remembrance of what did occur you cannot assist the Commission in any way, by enabling them to ascertain from the persons themselves, when and where, and with what object they performed these vivisections, if they did perform them?—I am sorry to say you may just as well inquire into Freemasonry. I only mean in saying that to show the difficulty that there would be in getting such information.

4229. (*Mr. Erichsen.*) In reference to this experiment of M. Paul Bert's, I see that it is stated here that the pneumo-gastric nerve was laid bare and tied, and that the sciatic nerve on the same side was laid bare and tied. Now, supposing the animal was sensitive, do you think that the tying of the nerve would be productive of much pain?—I should suppose that it was productive of much pain to do so.

4230. Have you ever seen during an operation a surgeon accidentally include in the ligature with which he was tying an artery, a twig of a nerve not bigger than a thread, and the intense agony occasioned by that?—I have never seen the thing, but I have been (as every student is) carefully cautioned against it on account of the great agony which it causes.

4231. (*Chairman.*) You have been asked a great deal about this experiment; is there any conceivable doubt that unless the animal was anæsthetised it was an excruciating experiment?—There can be no doubt in my opinion.

4232. And that that excruciating pain lasted over ten hours?—That this excruciating pain was continually kept irritated during the 10 hours and afterwards continued until death came.

4233. The period of the night during which the animal lingered being unknown?—Being unknown. It is a common thing, I may tell you, if a dog is not injured so that it cannot live, simply to keep the machine working all night, and in the morning it probably would have recovered from curari and can be set free; curari is eliminated by the kidneys.

4234. In the record given of this experiment the question of whether the pain was taken away or not diminished depends upon what may have been the action of curari in that respect?—It depends upon the action of curari.

4235. This experiment was performed in 1869, was it not?—Yes.

4236. As far as you know the opinion in 1869 was that curari did not act as an anæsthetic?—In the laboratory referred to I have heard it dozens of times pointed out while the animal was lying on the table, "Look at that animal; you would suppose "it does not feel, but it feels doubly." Three years after the date of that experiment such was the opinion of the people in that laboratory.

4237. If then there be any doubt at all stated in later years as to whether curari is or is not either an anæsthetic or a mitigator of pain, it can have no reference whatever, so far as their character for humanity is concerned, to the performance of these operations?—It can have no reference whatever to it. In that laboratory they have still that opinion according to the latest accounts from Claude Bernard.

4238. Is there anything else you wish to say before we terminate your evidence?—There was one thing which I thought I might perhaps explain to Professor Huxley in connexion with the writing of a thesis. On the last occasion, in answer to a question from him, whether it was not the case that students at Edinburgh on taking their degree often take for their thesis a subject requiring original research, I said it was "unfortunately true." What I meant by that is this, that I consider that this demand for a thesis is one of the most fruitful causes of vivisection. We know that when a man who has nothing to say is asked to speak he generally talks nonsense. In the same way when many medical men who have not got an idea are required to form a thesis containing such original ideas, not having them themselves, they go to look for them in the quivering bodies of animals. It is due, I believe, to the fact that in this country the great majority of medical men do not require to go through an university or read a thesis, that we have not so much vivisection going on here as they have on the continent, where every medical man has to do that; in France for instance, every medical man has to go through the University of France and present a thesis containing original remarks. It is that fact alone I believe which gives the continent a pre-eminence over England in vivisection, and it was with that in view that I said "unfortunately true." It has been really an incentive, causing people to make those experiments, and the consequence of that has been that such ideas being forced from individuals, as it were, have led to a very unsatisfactory state of things; that, not being men who had a special aptitude for the thing, but looking upon it as a necessity, they have gone into it; and the result has been what people might have expected. And I believe that this same feeling, that there is a very great deal more vivisection going on than is warranted is partaken of even by the very best of experimenters. I came across, to-day only, a remark by Claude Bernard on this same question, than whom there is not one better able to speak; there is not a physiologist whom I think a greater one, or one for whom I have a greater respect. He considers that there are not strict enough measures put upon vivisection; that people rush to do it and get the roughest results, and the consequence is that the whole of physiological science is so encumbered with a mass of contradictions, that people are apt to say that there is nothing found out in physiology.

4239. (*Lord Winmarleigh.*) Does Claude Bernard recommend any particular measures by which its unnecessary practice may be restricted?—He recommends none, but he deplores the excessive use of curari (I can say that much), in this same work, the *Revue Scientifique*, although he was the original introducer of it.

4240. But he does not go further than that?—No, he simply deplores that it is used too much.

4241. (*Mr. Forster.*) Does his statement that you have just been referring to lead you to suppose that he was arguing against the frequency of vivisection on account of the pain given to animals?—I understood simply that he meant that vivisection was entered upon by people who were not capable of doing it, and he deplores that there was nothing to prevent them.

4242. (*Mr. Huxley.*) I suppose that there is no very large proportion of the theses published in the University of Edinburgh which relates to experimental physiological subjects?—I understand there is a certain number.

4243. But in relation to the whole number of theses, it is a small proportion, is it not?—It is a small proportion.

4244. (*Chairman.*) Have you anything further to say?—I wish to say one or two things, with your permission. I wish to say a word about physiologists in consequence of the exaggerations that have been put out about them. From my experience, physio-

G. Hoggan, M.B.

30 Oct. 1875.

logists are not the monsters that some people picture them to be. Some of them are bad enough, but my own personal experience has taught me, and on the continent especially, that amongst physiologists you have the kindest, most gentlemanly, and amiable people, but that the glaring fault that was to be noticed was an entire want of feeling, that their feelings were entirely blunted; they seemed to be unconscious that they were inflicting the greatest pain; they did not do it intentionally. I wish to do justice to them by pointing out that it is a question of blunted feelings, not of a gloating in torture as has been represented. Then there is the question of performing experiments on animals before classes. If I may give an opinion upon that point, I absolutely deny that there is any truth in the proposition that it is necessary, or advisable, to fix physiological facts on the minds of students by exhibiting demonstrations of the same on the suffering bodies of animals. Demonstrations are certainly preferable to mere explanations or diagrams, but such may almost always be demonstrated by mechanism or by arrangements which inflict no pain. As an instance, I may say that I learnt as much about the nature of the circulation by the application of the sphygmograph to the wrist of the class servitor as ever I learnt afterwards in a public class on the continent by experiments on dozens of tortured animals, whose living blood vessels were tied on to the tubes connected with barometers for the same purpose. A chemist would be considered a lunatic requiring restraint who blew out the windows of his laboratory in order to impress on the minds of his students the effects of bringing a naked light into a room where a dangerous escape of gas existed; the customary experiment for this end being to mix the gases and explode them in a soda-water bottle. For the same reason, I would consider the mind of a physiologist perverted, and necessitating restraint, who with the sphygmograph at his disposal dared to torture a sentient animal in order to demonstrate the nature of the circulation upon it. I am, therefore, of opinion that demonstrations in class by means of painful experiments on animals, should be absolutely forbidden by law under heavy penalties. In cases where demonstrations are advisable they might be effected by means of mechanisms, into the devising of which the minds of ingenious physiologists would be directed when it was no longer possible to cause torture to animals for that purpose. Such a law would have a double advantage; it would protect animals from being tortured, and it would protect the minds of young men from the blunting and demoralising effects of vivisection. Then further I should like to express an opinion on the question of limiting permission to perform painful experiments in connexion with new discoveries only. I think this would be unsatisfactory, because while theoretically it would seem to be a safe precaution, practically it would be of no use whatever, as any experiments might be made to bear the desired interpretation.

4245. Have you anything further to say?—I think not.

The witness withdrew.

Adjourned to Monday next at 2 o'clock.

Monday, 1st November 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

Mr. ROBERT SAWYER called in and examined.

Mr. R. Sawyer.

1 Nov. 1875.

4246. (*Chairman.*) You are a member of the committee, I think, of the Royal Society for the Prevention of Cruelty to Animals?—I am.

4247. You are also a member of the profession to which Sir John Karslake and I, like yourself, have the honour to belong?—I am.

4248. You have been vouched here as a witness present at a lecture that was given by Professor Ferrier in Finsbury Circus?—Yes.

4249. And it is stated that you left the room with some others in consequence of the pain with which you saw the laughter of the young people. No imputation has been made, as I understand it, upon Professor Ferrier of actual cruelty, since it is understood that the experiments took place under complete anæsthesia, but it is stated in a paper put in by the secretary of the Royal Society for the Prevention of Cruelty to Animals, in answer to question 1569, that "popular lectures were being given of a sensational "character by a learned professor who made his "audience laugh over the grim behaviour of his "unfortunate victim"?—I do not think that that is the view that I took of it. I went to that lecture, because I heard that it was to be delivered, and I thought from what I heard that perhaps some experiments or operations would be performed, and I went there for the purpose of watching those operations or experiments, if there were any; I provided myself with a paper and pencil for the purpose of taking notes of anything that I saw there. As it turned out, no experiments or operations were performed, and therefore I did not take notes of anything that I saw; but I sat there through the whole of the lecture, and I took a position which was very close to the lecturer, intentionally, for the purpose of watching any operation. I was close enough to hear anything that was said, and I sat out the lecture. I do not suppose that the witness who said what has been read to me intended to express that I had left the room during the lecture, because, if so, he was certainly mistaken.

4250. He says, in answer to question 1576, "Three "gentlemen were with me who were members of the "committee of the society, and two of them left the "room at once in disgust"?—I did not leave the room at all.

4251. You were present during the whole time?—Yes.

4252. What have you to say to us with regard to what passed?—May I be understood first to say that I have not tendered my evidence, but that I am quite willing to answer any questions your Lordship chooses to ask me. I went there for the purpose which I have already stated. It appeared to me to be a very interesting lecture. Dr. Ferrier expressed himself extremely well, and he pointed out several things which were certainly very interesting. At the time that he was pointing out some particular part of the brain, and explaining that when that part of the brain was touched the animal that was operated upon performed certain movements with its legs and so on, he used an expression which certainly attracted my attention very much. He looked up to the people

Mr.
R. Sawyer.

1 Nov. 1875.

who were sitting above (we were in a sort of theatre, and I was at the bottom of it close to him), and he used this expression, as far as I remember, "I am "afraid to say how many cats I have operated upon "in the investigation of this." That is my recollection of it. It certainly struck me that Dr. Ferrier had brought himself into that state of mind that he considered that he was justified, no doubt he thought properly justified, in performing a number of operations with regard to that particular fact which he was pointing out to us at that time. When he made that observation there was a titter, and certainly an expression of feeling amongst the people, which I was disappointed to see. I was pained at the fact that the people did seem to look upon that assertion of Dr. Ferrier's with considerable levity. I really have no more to say than that, excepting to answer anything that your Lordship likes to ask me.

4253. Did it not appear from the lecture, whether these operations had taken place under complete anæsthesia?—I understood Dr. Ferrier to say, at the beginning of the lecture, when he was first explaining to us how the operations were performed, that after removing a portion of the skull the brain might be cut and touched for the purpose of exciting certain movements, and so on, but that the animal felt no pain.

4254. Then that impression would be derived, I presume, by that portion of the audience who paid proper attention to the lecturer?—I should think so.

4255. So that those who laughed when this remark was made may presumably have been under the impression that all these animals had been deprived of sensibility before the operation, in its nature painful, had been performed upon them?—In the opinion of Dr. Ferrier, certainly.

4256. Do you consider, summing it all up, that there was anything in what Dr. Ferrier said which implied an indifference to pain on his own part, or a desire to promote indifference to pain in the minds of his audience?—No, I should think not. The thing that occurred to me, rather, was that Dr. Ferrier would consider himself justified, in an investigation of that particular phenomenon, in taking away the lives of any number of animals, but that he would say, I suppose, in justification of that, that the animal was not suffering pain.

4257. (*Lord Winmarleigh.*) Did I understand you rightly to say that Dr. Ferrier said that the animal, after the operation you have mentioned, suffered no pain?—I understood so.

4258. Did I rightly understand you to say that Dr. Ferrier had, in the course of his lecture, stated in any way that the operation had been under anæsthetics?—I understood him to say, at the beginning of the lecture rather, when he was describing how part of the skull was cut off so as to expose the brain, that it had been done under anæsthetics.

4259. (*Sir J. B. Karslake.*) Might I ask you who attended with you on this occasion of the Royal Society?—Mr. Colam was there, Mr. Reid Thompson, and Mr. Thomas Allen of the South Wales circuit.

4260. Did you all leave in company?—I think not.

4261. Is it new to you that any one of the gentlemen who attended with you upon that occasion, by appointment probably, left before the lecture was over?—It is new to me.

4262. At all events, you were not one of those who left?—I was not.

4263. Were the others sitting near you?—No.

4264. About how many persons were present, do you think, as far as you could judge?—I have never thought of that at all, but I should think it must have been 50 or 60, or 70; a considerable number, certainly.

4265. And of different ages, varying from quite young people to people of considerable age?—Yes.

4266. And the thing that occurred to you during the lecture, and which you regretted to find existing, was a certain levity of conduct on the part of the audience, when the professor spoke of the number of animals that had been sacrificed for the purpose of obtaining these particular results?—Yes.

4267. Did he refer, do you recollect, particularly to a monkey, and show a diagram of a monkey?—There was no diagram of a monkey; there was a diagram of a monkey's brain, and diagrams upon the wall of a number of brains of different animals.

4268. Was the whole argument which the professor was using that, notwithstanding a complete absence of sensory feeling on the part of the animal, it gave indications by its movements of feeling which he knew that the animal did not feel?—I can hardly say that. He said that it gave indications of feeling, certainly.

4269. Was not the argument this, that although there had been measures taken which prevented the animal from feeling, yet on touching particular parts of the brain the actions of the animal would be such as would exist if the animal had feeling?—Yes, I think so.

4270. Had you attended other lectures at the same place?—None at all.

4271. And you went with the expectation of seeing animals actually operated upon in the room?—I can hardly say with the expectation, I went there for the purpose of taking notes of any operation that might be performed.

4272. With the exception of what you say was the conduct of some part of the audience in tittering when they heard that many animals had been sacrificed in the establishing of a particular theory, was there anything in the lecture that struck you as not worthy of a lecture from an able and scientific man?—Not at all; except this, that Dr. Ferrier, I thought, showed indifference to the fact that he was taking away the lives of a great number of animals.

4273. Did you collect from him that he had performed a single experiment which was unnecessary for the purpose of establishing the fact, if it was important to establish that fact?—No, not at all.

4274. (*Mr. Huxley.*) You were sitting quite close to the lecturer, you say?—Yes, as near as I am to you, I think.

4275. May I ask, as a matter of fact, if he laughed himself?—No; he did not laugh himself, but he smiled; he looked up in this way (*describing it*), and smiled at the people at the top circle of the theatre, so to speak.

4276. Would you say that this, which I find in the answer to question 1588, was a fair description of Dr. Ferrier's course of action, that "the skill of "the lecturer was used to cover the grim character "of the experiment by his humour?"—It did not strike me so. I believe there were two lectures; I was only there the first day; it was the 1st of February that I was there.

4277. (*Sir J. B. Karslake.*) Were you a party to that report which was read to us?—I am no party to any paper which is directed to your Commission; I do not remember ever having seen one. It may be that that commencement, the direction "To the Royal Commission," may have been appended to some paper to which I was a party, but I am not aware that any instructions were given to Mr. Colam to bring a paper to the Commissioners at all. It may be that at some committee meeting at which I was not present, some direction of that sort was given. I think it likely that I have not attended any committee meetings since the Royal Commission was issued.

4278. Referring to the words which have been read just now by Mr. Huxley, let me ask you, were you any party to a report in which that language occurs?—I think not. I must be taken to be a party to a report which was made by the sub-committee, and which was read in my presence, but I have no recollection of such expressions as that being used in the report.

4279. (*Mr. Huxley.*) Were you a member of a committee which was appointed by the Royal Society for the Prevention of Cruelty to Animals upon the

Mr. R. Sawyer.

1 Nov. 1875.

presentation of a memorial against vivisection?—I was a member of the committee.

4280. Then according to the statement that appears in our printed evidence, one would be led to conclude that that is the very report of which you have just heard a portion read. I will read you the answer of the Secretary in order to show that. At question 1567 he is asked, "Is there anything that you desire to bring before the Commission which has not been included in the questions already put to you?" and his answer is, "I do not know that there is, excepting that I was rather anxious first of all that you should understand that the Royal Society for the Prevention of Cruelty to Animals is not the society established for the total abolition of experiments; and secondly I was instructed when I came here to read to you what the committee which was appointed by the Royal Society for the Prevention of Cruelty to Animals did upon the presentation of a memorial against vivisection, in reference to the examination of the allegations of the memorial, and the deliberations upon its prayer." Then the next question is, "That is a document prepared under the sanction of the society, and you are speaking their language when you read it to us?" And the answer is, "Yes." And then the witness proceeds to read the document, a portion of which you have just heard. Now, whether you were a member of the committee here referred to or not, you have not had the passage which has been read under your consideration?—I was a member of the committee which we call the sub-committee on vivisection.

4281. But whatever committee you were a member of, that particular passage which has been read was not submitted to you?—I do not remember that "grim" part.

4282. (*Mr. Hutton.*) In answer to question 1576, Mr. Colam said of Professor Ferrier, "I have heard him say that the animals appeared to be in intense suffering, and then joke about the stupidity of the animal, especially if the animal happened to be a monkey, giving humorous descriptions of its behaviour, so much so that the whole lecture place was really like a comic scene;" and on that I put a question to him afterwards, at Question 1606, asking him to explain his statement, that the lecturer joked about the stupidity of the monkey, and asking him this: "Those movements were involuntary, were they not?" And he said, "Of course they would be, because he showed that the animal had no volition at all." "And therefore," I said, "it was meant as sort of joke upon the apparent expressions of the monkey?" To which he replied "Yes, the loss of intelligence of the animal." Now do you remember anything of that, and did it strike you that there was levity in that description of the loss of intelligence on the part of the monkey?—I do not think that that occurred at the lecture that I was present at at all.

4283. You think it must have been at the other lecture?—I think so.

The witness withdrew.

Mr. Joseph Lister, M.B., called in and examined.

Mr. J. Lister, M.B.

4284. (*Chairman.*) You are Professor of Clinical Surgery in the University of Edinburgh?—Yes.

4285. And Surgeon in Ordinary to the Queen in Scotland, and a Fellow of the Royal Society?—Yes.

4286. I think I may also ask you if you are a son-in-law to the late Mr. Syme?—Yes.

4287. And you have not only had a good deal of experience yourself in the matter which has been referred to us, but much of that experience was in the society of that very eminent surgeon?—He was well aware of what I did in these matters.

4288. He performed, I think, some experiments himself?—Yes, very important ones.

4289. Was that before the time of anæsthetics?—Yes.

4290. Can you tell us, in the first place, whether I am right in saying of him that he was very desirous to promote humanity in the treatment of animals in this particular as far as possible?—Undoubtedly he was.

4291. You have had then very considerable experience upon this subject?—Yes, I have.

4292. Now at the present time, what is your opinion about the necessity or otherwise of experiments on living animals for the purpose of ensuring the progress of physiological and surgical and medical knowledge?—I consider them one of the most important means that we possess for those objects.

4293. Can most of the experiments that are necessary in your judgment be performed under chloroform?—In the case of the higher animals the majority can undoubtedly.

4294. Of those that cannot, is it a frequent case that the more painful parts of the experiments can be performed under chloroform?—It is certainly. The operation may be performed anæsthetically, and the results witnessed afterwards.

4295. Where you perform the operation itself under chloroform and then retain the animal alive for witnessing the consequent results, is it usually a very painful period to the animal while you are witnessing those consequent results?—In my own experience it has as a rule not been so. The wound itself has as a rule been free from inflammation and from pain.

4296. Then is there a residuum of experiments which are in your opinion necessary and which must be painful?—I cannot doubt that there must be such.

4297. Are those experiments, do you think, of protracted agony on the part of the animal?—Not as a rule; but it is impossible for me to foresee what the requirements of physiological science may demand.

4297*a*. If such experiments were to be held to be necessary, and were to be performed at all, I need scarcely ask you if they ought to be performed by the most highly educated and most competent persons?—Undoubtedly.

4298. And whether for science itself that is not as essential as it is for humanity?—Certainly.

4299. Now I gather from what you have said, that if the Legislature should interfere for the purpose of proposing any check upon such experiments, it would be a first consideration with you whether that legislative measure interfered with any experiments which you thought necessary for the progress of physiological knowledge?—Yes. I should feel it a very doubtful matter whether any legislative interference could take place that would not hamper in an undesirable manner such investigations.

4300. But your objection would probably depend upon whether or not such impediments were thrown in the way?—Undoubtedly if there were no impediment thrown in the way of investigation, I could have no objection to legislation.

4301. If there were no impediments thrown in the way, that is to say, of the prosecution by the most scientific and educated persons of such experiments as might be absolutely necessary for the progress of physiological science?—It is sometimes difficult to define who are the most scientific and competent persons. Some private practitioner, for instance, who might be an obscure person to the profession generally might yet perform experiments that might be very valuable.

4302. That is a conceivable case; but within your knowledge has it ever been an actual case?—It is not in my knowledge that any such experiments have been performed except by persons of scientific competence.

4303. Then probably all the persons of scientific competence are at this moment known by name to yourself, for example?—Well, any man who has

Mr. J. Lister, M.B.

1 Nov. 1875.

had a thoroughly good education as a medical student I should conceive to be competent. I should think it would be a mistake to throw any barrier in the way of his performing investigations that he desired. If I may be so egotistical as to refer to myself, my first experiments were performed when I was altogether unknown as a person of any sort of reputation whatever. When I first took in hand to teach others, I felt that there were some points on which I desired more information than I could get satisfactorily from any book, and my first experiments were performed with the object of preparing myself for teaching, while I was not a person of recognised scientific attainments.

4304. You performed them with the knowlege and under the sanction of Professor Syme, did you not?—The first that I did were not with his knowledge at all.

4305. (*Mr. Erichsen.*) But you had already been appointed a teacher?—I had been appointed a teacher.

4306. (*Chairman.*) And, speaking generally, you have said that your experiments were performed with the knowledge and under the sanction of Professor Syme?—Not in the least by his direction. I only mean that I used to converse with him on what I was doing, and that what I did had his warm approval. I said that with reference to his character, which I do not wish to be misunderstood. I meant that while he very much disapproved of anything like cruelty or the infliction of needless suffering, he, on the other hand, highly valued such inquiries when legitimately conducted.

4307. (*Lord Winmarleigh.*) Have your practical experiments on living animals been attended by a numerous audience?—No; they have been entirely for my own private investigation.

4308. You have not lectured on the subject?—I have shown a demonstration before now to a class, many years ago.

4309. But you have not been in the habit of doing it?—No.

4310. Have you been in the habit of attending much at lectures or experiments performed by others?—Not since I was a student.

4311. In your experience, have you ever witnessed the effect that the experiments have had upon the young men who attended the lectures?—Not except in my own courses of lectures, which were then delivered to small classes. The influence was, so far as it went, highly beneficial.

4312. In what way beneficial?—Because a demonstration of an actual object gives information which description cannot give.

4313. But you have never seen any experiment or demonstration which has caused any laughter on the part of those who attended it?—No. I remember the flood of light thrown upon Dr. Sharpey's physiological class by his demonstration to us of the effects upon the circulation of the division of the sympathetic nerve in the neck; how intensely interested we all were, without, certainly, the shadow of levity on the part of any one of us.

4314. Should you believe that amongst the attendants on the lectures that are demonstrated by experiments it is the habit to show any levity?—I have never heard of any such thing.

4315. (*Sir J. B. Karslake.*) I think you said that in your opinion experiments on living animals will necessarily be carried on extensively hereafter, and many of them of a character which you cannot suggest at the present time?—Yes.

4316. That must remain to be determined by the necessity pointed out by experience?—Yes.

4317. How long ago is it since you yourself lectured, and had to perform experiments or to show living animals to your class?—My last experiment was performed about six months ago.

4318. I refer, not to private research, but how long is it since you have demonstrated to a class by means of animals under chloroform or other anæsthetics?—Well, it dates back to the beginning of my lecturing, before 1860.

4319. All your lectures have been given since chloroform or other anæsthetics have been in use?—They have.

4320. I think I understood you to say that you have used very few experiments upon living animals for the purpose of demonstration?—Very few; it has not been much required in my department of teaching, which is that of surgery.

4321. Is there any particular branch of surgery in which you teach?—I now teach practical surgery. I used to teach the whole subject, and then, in illustration of the more fundamental parts, the pathological parts, I used to find illustrations of that kind useful.

4322. But in the teaching of surgery it is less common, is it not, than in other things?—Very much so indeed.

4323. You teach chiefly by the dead subject?—Yes, or in my case now upon the living subject.

4324. With reference to the question put to you by Lord Cardwell as to these experiments being only those which are absolutely necessary, and which are performed by competent persons; in your opinion, would persons who were competent sometimes perform these experiments, although they were unknown to fame at the time they were doing it?—I certainly think so.

4325. And there would be a difficulty in excluding those persons?—That is my feeling. I do not think that anybody who was not connected with a school would be likely to perform such experiments, unless he had in him such an ardent love of the pursuit of physiological truth as it would be very undesirable to check by any legislative enactments.

4326. (*Mr. Huxley.*) Take the case of another science. Suppose that there was any legislative interference with the freedom of persons unknown to fame to perform some experiments in chemistry, we should then in all human probability have entirely lost Davy, I presume, and Faraday?—Precisely so.

4327. And there probably will be in your judgment no great reason for believing that there is such a great difference between the physiological sciences and others that the same consequences might not follow there?—That is very much my feeling.

4328. I should like to ask you what is your own feeling about causing pain to animals without some clear and definite purpose in view?—I think there ought always to be some clear and definite purpose in view. At the same time I must confess that if we consider the sort of objects for which pain is commonly inflicted upon the brute creation, as for example in the castration of male animals merely for the purpose of making them more easily fattened and their flesh better fitted for food, or, in the case of the horse, more patient and docile drudges, (these operations are exceedingly painful and often involve considerable suffering afterwards in the way of inflammation, and the objects in view are not essential to man's existence, they merely promote man's luxury and man's comfort;) if for such purposes painful operations are performed, without any objection,—in fact it is universally admitted that such procedures are legitimate,—as compared with objects like those, I confess that to myself even a demonstration of a physiological truth, as distinguished from an investigation, seems to me to rank higher. I believe that this matter ought to be considered, not so much with regard to the actual pain caused to the animal, as with reference to the effect produced upon those who inflict it, or those who witness the infliction. I think that for students to have unnecessary infliction of pain practised before them would be highly demoralising; and therefore from that point of view I think that such demonstrations should be performed, where they possibly can be, under anæsthetics; but that not so much for the purpose of avoiding pain to the animals as for the sake of avoiding a demoralising influence on the students. For after all I suppose that the actual pain caused by all the vivisectional experiments that take place throughout Great

Mr.
J. Lister,
M.B.

1 Nov. 1875.

Britain in a year would not amount to the pain that results from by the winging of pheasants in a single day's shooting on the battue system. There it is considered legitimate; whether it is so or not is another matter; but as compared with what is ordinarily regarded as legitimate, the actual pain caused by vivisection is in truth insignificant. It comes to be of very great importance in its influence on the mind of the student, but I think that is the really essential point of view.

4329. I presume from what you have said that you yourself would think it morally wrong to inflict needless pain upon any animal; that is to say, if you had the alternative of being able to administer chloroform in a given experiment or not, you would think it your duty to administer it?—If I could attain the object of the experiment as advantageously; but not otherwise. This is a subject on which I have thought and felt a great deal; and I may say that I have often performed these experiments at very great sacrifice to my own feelings; but I have believed that the consideration of the probability of good being gained to the human race was a higher consideration than my own personal feeling in such a matter.

4330. Your acquaintance with men following experimental physiology will doubtless be extensive; what is your judgment about the feeling on those matters of the persons whose opinions you have reason to know?—My own impression is that medical men are the most humane class of the community. Their whole lives consist in acts of beneficence which bring out their best feelings; and I think that there is no class of mankind who would be so likely to feel tenderly for a lower animal as medical men. Such a man knows what the suffering is and appreciates it no doubt more truly in some respects, and would sometimes think less of the suffering than some other persons might; for example, he would know that a frog would not suffer like a man; but still with reference to the suffering, such as it is, I believe nobody would feel so tenderly as a medical man.

4331. I presume that if anyone told you that he would not administer an anæsthetic except for his own convenience, you would not approve of that sentiment?—Certainly I should not; at the same time I would not push the thing too far. For instance, suppose a small operation had to be performed on a horse's neck, involving a small incision and not much pain consequently, it is a very laborious thing to put a horse under chloroform, and I would not judge a man too hardly who under such circumstances said "On the whole I think we need not give chloroform here." I think we must not draw too strict a line of that kind.

4332. That was not the case which I had in my mind; I had in my mind the case of a severe experiment where chloroform could be administered easily?—Undoubtedly, I should think it a duty under such circumstances.

4333. (*Lord Winmarleigh.*) Would the administration of chloroform occupy much time?—It occupies a considerable time in the horse; a large animal like that takes a long time.

4334. And in the dog or cat, or rabbit, does it take long?—No, not very long.

4335. How many minutes should you say it would take to put a rabbit under chloroform?—Four minutes, perhaps.

4336. And a dog?—I could not say exactly; not any very long time.

4337. It would not be a material interruption, then, to any experiment on those animals?—No.

4338. (*Mr. Huxley.*) I understand that you consider that experimental physiological research has borne, and is likely to bear, very important practical results. Could you enforce that by anything within your own knowledge?—Well, perhaps the best way would be to take my own actual experience. The experiments to which I have referred before with reference, in the first instance, to teaching a class, had the effect of giving me a kind of pathological information, without which I believe I could not by possibility have made my way in the subject of antiseptics; and that subject, I believe, is becoming recognised as one of considerable practical importance. I have often felt that without the basis which I derived from experiments on the lower animals, I should never have been able to thread my way through the very perplexing and apparently contradictory facts which I met with in the first instance.

4339. I understood you to attach a very great value to actual demonstration of facts in the teaching of science, as far as can possibly be carried?—Yes.

4340. I suppose that in the teaching of surgery, which is your own special subject, although it is quite possible by the aid of clear descriptions and figures to give a student as good an idea of an injury as you can give of most things by mere talking about them, you would look upon the state of mind of the man who had heard an injury described, and that of one who had actually seen it, as very different?—Very different indeed.

4341. It is hard to describe the difference, and yet do not we know that it is, I might say, almost infinitely different?—It is inconceivable what a great difference there is.

4342. And as a matter of fact, in your branch of medical science, as in all others, the examining bodies very justly insist upon every student having had at least the opportunity of becoming pratically acquainted with the facts of disease?—Yes.

4343. And I presume that if any suggestion were made that such opportunity of occular inspection should be omitted, that would be regarded as a very retrograde step in medical education?—Undoubtedly; the tendency now is to insist more and more upon everything, as far as possible, being made practical and demonstrative in the way of instruction.

4344. Have you thought of a proposal that has been made to prevent all painful experimentation upon animals, that is to say, experimentation except under chloroform or anæsthetics, except in the case of those persons who may be provided with a license?—I have thought of that, and I confess that it has not seemed to me that any such legislation is called for. I am not aware of any temptation existing in this country to experimentation of that kind by persons who are not competent for it.

4345. In fact you think that it would be superfluous legislation?—I think it would be superfluous; and not only so, but personally I should feel it a sort of blot upon our profession, as implying that such legislation was necessary, which I believe it in this country not to be.

4346. You would feel, as you have just now expressed yourself, that a large amount of suffering is being inflicted for various purposes, and which is not meddled with, and that the only persons who inflict suffering for beneficial purposes would be meddled with if such a proposal were carried out?—They would be if that were so.

4347. Can you state to the Commission if that is the general feeling, so far as your experience goes, among members of the profession?—The few that I have talked with on the subject have, I think, that feeling.

4348. A suggestion has been made, on which I should very much like to have your opinion as a practical investigator and teacher of large experience, namely, that no experimentation of this kind should take place except in laboratories, and that the laboratories should be provided with a gallery, and that to that gallery the public should be admitted. Do you think that that suggestion is at all one which is likely to commend itself to those who are occupied in teaching or in investigation?—I should feel a very strong objection to it myself. In the first place (to allude to myself again), under such a rule, my experiments could not have taken place; they were not done in physiological laboratories at all; I should not have had the opportunity of doing them in any physiological laboratory. And in the second place, I think of all

Mr.
J. Lister,
M.B.

1 Nov. 1875.

undesirable things the most undesirable is that the public should witness these things; because they would simply see what they would not understand, and would suppose that very dreadful things were taking place, when they were in reality perfectly proper; and no advantage could possibly be derived, that I can see, from the public witnessing these things.

4349. That is to say, in point of fact, very innocent things might be done which would give them the impression that very horrible things were being done; and, on the other hand, very horrible things might be done which would give them the impression that very innocent things were being done?—Undoubtedly.

4350. (*Mr. Erichsen.*) Am I correct in understanding that in all your various capacities, as practitioner of surgery and as a teacher of surgery, and also as a man who has been foremost in the advance of surgical practice and science, you have found experimentation on living animals necessary?—That has been so.

4351. And that through the medium of that experimentation, originally commenced possibly, I think I understood you to say, with other views, you were gradually led to the development of that method of treatment which is now known as the antiseptic system?—Yes.

4352. That in the pursuit of that inquiry you were led to ligature the arteries of some of the larger animals?—Yes.

4353. Am I right in thinking that it was necessary that you should discover some substance to use as a ligature which did not produce the irritation which is occasioned by an ordinary ligature?—Yes.

4354. That was an essential part of the business?—It was.

4355. And that could only be ascertained by experiments on living animals?—Yes, certainly.

4356. Had you not made experiments on brutes, you would have had to experiment on man; there was no alternative, was there?—There was no alternative.

4357. You could not discover such a thing as an antiseptic ligature, for instance the antiseptic catgut ligature, by any *à priori* reasoning?—It must be tested by experiment.

4358. In ligaturing these larger arteries in large animals you used, I believe, calves, horses, and animals of that kind?—Yes.

4359. Will you tell us whether that operation of the application of a ligature to the large arteries of a large animal is a painful process?—As it was performed with that particular object it did not involve pain after the performance of the operation, as there was really no inflammation.

4360. The animal could be anæsthetised during the operation?—During the operation it could be anæsthetised.

4361. We have been given to understand that the after effects of the application of the ligature to an artery are extremely painful, is that so in your experience or not?—It is certainly not only contrary to my experience in the lower animals, but contrary to my experience in the human subject.

4362. It is your opinion, that if the ligature is carefully applied, neither in the man nor in the animal are the after effects painful?—Yes; especially if, by antiseptic management of the wound, the occurrence of inflammation is prevented.

4363. Do you think that experiments on such animals as dogs, calves, and horses, and animals of that description, form a safe analogy to the corresponding results in man?—I must say I think they do. I have seen precisely the same effects follow in man that I have seen in the lower animals.

4364. If you apply a ligature to the artery of a dog or of a horse, and that animal is killed some days afterwards, is it the case that you would find the same appearances, as nearly as possible, as if a ligature had been applied to the artery of a man who had died some days afterwards, not in consequence of the operation, but perhaps from the effect of an injury or whatever the cause might be?—Certainly.

4365. So that there would be a close analogy between experiments upon the larger animals and upon man?—Yes.

4366. And it would be safe to deduce an inference from the close analogy that exists between the two?—I think so.

4367. You stated, I think, that you do not think that experiments on the lower animals produce hardening or demoralising effects upon students, those who witness them; that is the result, I think, you stated, of your experience in a very large medical school?—Yes, if done as any humane teacher would do them.

4368. That the mere infliction of pain, even if it were necessary that pain should be produced, would not necessarily demoralise or harden the student?—Certainly it would not if it were done under a proper feeling.

4369. I am supposing that it is done in a solemn manner, as it were, by a man perfectly competent to do it, and with every possible precaution, but yet that pain was the inevitable result?—Yes, I understood the question in that sense.

4370. I think that you are not old enough to recollect the operations on the human subject before the introduction of anæsthetics?—I saw Liston do the first operation ever performed under chloroform in London. I was then a junior student in University College.

4371. From your knowledge, you must be aware that there were most dreadful and painful scenes witnessed every week and almost every day in the operating theatres of all the large hospitals?—Yes.

4372. Do you think that the surgeons who witnessed and were participators in these scenes, the surgeons, in fact, of a past generation, and those who were educated at that period, were less tender-hearted or less humane than the surgeons of the present day, who perform all their operations under the influence of anæsthetics?—I do not. I may take, for instance, Mr. Syme's case, his name having been already mentioned. Mr. Syme was a most tender-hearted man: as a man of a feeling heart, I would put few before him; and yet more than half of his surgical career was before the time of anæsthetics.

4373. He had a most active surgical career, and had been a great operator before the year 1846 or 1847, when anæsthetics were introduced?—Yes.

4374. In performing these experiments on the lower animals, you have hitherto spoken of the larger animals. Have you ever had occasion to experiment on the frog?—Yes, very much.

4375. Do you think that the sensibility of the frog is as exalted as the sensibility of those larger animals which we have just been speaking of?—Undoubtedly not. Perhaps I might illustrate that subject by examples. The lower we go in the scale of animal organisation, the lower is the sensibility. I remember being very much struck, when a medical student, with the following circumstance. I had some marine animals for observation in a vessel of sea water, some of them attached to a piece of rock; and out of a crevice in the stone there happened to come a very long sort of sea worm, and the creature's tail was still in the rock while the head was moving about, as if in search of food. I wished to draw the animal out to see what the tail resembled, and I took hold of it near the tail with a pair of forceps, necessarily pinching it extremely severely; yet the front of the creature continued its exploratory movements, absolutely unaffected by the very severe treatment of the part near the tail. I was very much struck, I recollect, by seeing that. Then if we proceed higher, take, for instance a fish, to which a frog is closely allied in organisation, it seems to me that the way in which a salmon pulls when it has taken the fly is as good evidence as any experiment made for the purpose can afford, that the sensibility of the tongue and the interior of the throat is altogether different from that of the human subject. Supposing a man were caught by a sharp hook in the tongue or interior of the throat,

Mr. J. Lister, M.B.

1 Nov. 1875.

he could not by possibility pull, as the salmon does, against the hook; the torture would be so exquisitely great that it would be an impossibility for him to pull in that way. That is one instance; but it seems to me that it is only one among many that might be given which are perfectly conclusive on the matter.

4376. There is no evidence of the animal in that case suffering any particular pain, but he tries to escape, he is restrained, and he is in an uncomfortable position, just as he would be if put into a basket?—Supposing we really believed that a fish when hooked suffered as a man would suffer, it would surely not be legitimate to set a long sea line and let cod and other fish remain attached to its hooks for hours together. Nor should we be justified in putting a lot of herrings down in the bottom of a boat, if we supposed that they would suffer in their death as the persons put into the Black Hole of Calcutta suffered. I am astonished that there should be any doubt on the question.

4377. (*Lord Winmarleigh.*) You said that hundreds of other instances could be given. Could you give us some one or two more?—I have been told on good authority, that a crab in a vivarium was seen eating food, while another crab was eating the posterior part of the eater. There is a practice familiar to boys, which is this: Take a dragon fly and take off the abdomen, and then give the creature food, and see it swallow. The food passes out through the gullet and the creature goes on voraciously eating, its appetite never satisfied.

4378. Have you seen that experiment done?—I have not, but I have known it done.

4379. (*Mr. Erichsen.*) In your experiments on frogs, you have not found it necessary as a rule to anæsthetise them by chloroform or ether?—There is great inconvenience in the use of chloroform, because it stimulates the frog's web and produces inflammatory action.

4380. In an animal like the frog (we will keep to the frog at present), would you take the movements of the animal kicking, struggling, and so on, as necessary indications of pain?—Certainly not, because they go on after the frog's head has been removed.

4381. Or the spinal cord divided?—Yes, the spinal cord divided next the brain.

4382. (*Lord Winmarleigh.*) At the same time, when a dog is flogged with a whip, or struck with the foot, or hit with a stick, he shows, does he not, by his howling, and by the mode in which he crouches and puts his tail between his legs, that he does suffer very great pain?—The dog is of course in a very different position from the frog; very much more highly organised, and correspondingly much more sensitive.

4383. I collected from what you said before, that the lower you go in the animal creation the less sensible the animals are to pain?—Yes; but the dog being comparatively high in organization, is correspondingly high in sensibility.

4384. Take a worm?—I have taken one instance of a worm.

4385. Take a worm put on a hook; when it writhes about, are you of opinion that that worm does not suffer pain?—I am of opinion that the suffering there is probably almost nil.

4386. How do you prove that?—The analogy of all physiology proves it. The mere movement to which Mr. Erichsen was referring just now is in itself no necessary indication of suffering; just in the same way as in a paralysed man, where there is absolutely no feeling, pinching the leg or tickling the foot will often cause the leg to kick violently, without there being the slightest feeling on the part of the patient.

4387. (*Mr. Erichsen.*) Or without his being even conscious of the limb moving?—Yes.

4388. (*Mr. Hutton.*) But you would not argue, would you, that because a paralysed man kicked violently when he was not conscious of the suffering, it was no proof, if he were not paralysed, that he felt pain? You would not argue from the reflex action in the case where the man was not suffering, that it did not prove that he was suffering in case he were not paralysed?—Of course not. I only take that as absolute evidence that movement does not necessarily imply suffering.

4389. You mean to say, that it does not necessarily prove it; but still, if the frog were whole and perfectly unparalysed, as far as you know, it would rather be evidence that it does suffer, would it not?—Not evidence that it did suffer. For example, take the sensitive plant; I do not suppose that anybody imagines that the sensitive plant suffers when the leaves are so stimulated as to induce them to contract.

4390. Still, the frog is comparatively very high in the order of organised beings. It has a very large proportion of nerve system to its whole being, has it not?—The brain is not very large in proportion to its whole being.

4391. But the nervous system on the whole is, is it not? We have had it called the physiologist's animal on that account. Is it not selected as the physiologist's animal because it has so considerable a proportion of nervous system to the whole being?—I do not think that is the reason that it is selected. It is selected for its convenience, because it is so tolerant of severe treatment, and also undoubtedly largely from the fact of its being not supposed to suffer materially.

4392. Then we have been told by a veterinary surgeon that frogs do show every sign of very considerable suffering under the influence of parasites; and from that he argued that the frog probably was not so low in the scale of sensation as you have just been representing it?—It would be very difficult to prove that frogs *suffer* from parasites.

4393. You were saying that you personally, and that a great many of your colleagues, would think it a blot on the profession if any restriction of any kind were to be imposed. Now do you think that the factory owners would be justified in thinking it a blot on their profession that certain restrictions were imposed upon their employment of children?—Well, perhaps if I were a factory owner I might feel it rather a blot upon myself.

4394. Do not you think that these are the conditions under which legislative restraint is sometimes allowable, that the interests of the creatures whose welfare is at stake cannot be defended by themselves, and that these interests run counter to the interests of the persons who cause them the suffering, or who are liable to cause them the suffering. That is the case with the factory children, for instance; they are not able to defend their own interests, and their interests and those of the trade are at issue and in conflict. Now is not that equally true of this particular case, that the interests of physiologists in the advancement of knowledge, and the interests of the animals which are experimented on in order to advance knowledge, are in conflict with each other?—I do not think it equally the case. I believe that there was a case for the Factory Acts, as far as I have understood, but I do not think that there is a case for any action here.

4395. Now you have said very justly that the medical profession are probably the most humane in the world; but is not that, in a very great measure, because the whole object of their effort is to diminish suffering. That, I suppose, is one of the chief reasons, is it not, why they are so humane; that they are engaged in diminishing suffering?—Yes. They are brought into circumstances in which their best feelings are brought out for the relief of suffering, mental as well as bodily; their sympathies are evoked, as it were, whether they will or not.

4396. Now that does not apply in any way, does it, to the class of physiologists who are engaged in extending knowledge by these inquiries, and not engaged in healing, &c.?—Well, it applies less, of course, in proportion as a man may be more purely devoted to abstract physiological inquiry. If he is not engaged at all in medical practice, of course, in

Mr. J. Lister, M.B.

1 Nov. 1875.

so far as it does not apply to him, further than his medical instruction had a humanising influence upon him as a student.

4397. Therefore in his case you have not the guarantee that his whole life is bent on diminishing suffering?—No, certainly not.

4398. And a very large class, an increasing class, of physiologists are springing up, are they not, in this country, and are likely to be needed?—I think it very likely that there are.

4399. I understood you to say that you were very much afraid of diminishing the number of private inquiries of this kind. Now it has been given in evidence by a very eminent man here that if nine tenths at least of this sort of original research were strangled the remaining tenth would be all that anybody would find any advantage from. Does that in any way agree with your knowledge of the original research that has been going on?—No, I should not give such a proportion as that. But besides that, supposing it were true, it would be impossible for anybody to say which was the one tenth that was to be encouraged, and which were the nine tenths that were to be discouraged.

4400. It would be very difficult no doubt?—Impossible.

4401. Still if you are to prevent an immense amount of suffering to animals that is useless, you must set against that, some disadvantage in checking investigations that might be useful?—I do not think you can properly describe it as "an immense amount" of suffering to animals. If you compare it with what animals suffer from being caught in traps and in various sorts of ways injured in the ordinary circumstances of human life, not to mention what they suffer in death from natural causes, cold and hunger and injury and disease, that which vivisection occasions is an absolutely insignificant amount in the abstract.

4402. But though an insignificant amount in this country, it is not at all an insignificant amount in other countries, and it may become a very significant amount in this country?—If it ever should be so I should think it would then be time enough to think of legislation.

4403. And not at the time when the danger is beginning to occur, when we are actually getting a new school of men who are not employed in diminishing suffering, but who are employed in merely investigating physiology as a pure science?—I do not believe that there would be any danger of persons engaged in that way in this country prosecuting it in any inhuman spirit.

4404. But now let me ask your opinion of an investigation which we have had a good deal before us, in which a dog has been subjected to eight or nine hours suffering, of the amount of which it is exceedingly difficult to form an opinion (some witnesses have told us it was very great, and some have told us it was very small), for the purpose of discovering the power of rhubarb in increasing the secretion of the liver. Now assuming the suffering were very great, do you think that is a sufficient end for inflicting eight or nine hours of pure suffering on the dog?—I must say I do. The other day I saw in the country a rat that had been caught by two legs in a rat trap, the creature must have been suffering for hours; that is a kind of thing which is going on all over the country, and which you can never stop. Now the suffering there is very much greater than the suffering in the case that you mentioned.

4405. But still it is not suffering consciously indicted?—The one is suffering consciously inflicted for a noble object, the other was thoughtlessly inflicted for the comparatively ignoble and selfish object of keeping the rat from stealing fruit.

4406. But I thought you said just now that you considered that the fact of its being consciously inflicted was a great additional mischief?—Not the fact of its being consciously inflicted, but *unnecessary* suffering inflicted consciously.

4407. You would not think it in itself an evil, the mere fact that it had been consciously inflicted?—No, if a man has a due sense of his responsibility and the importance of the object before him.

4408. Not even though the creature itself is not the object of his sympathy, but is sacrificed to some remoter object of symyathy?—I still think so. Take for instance such a case as this: suppose a race horse had some tumour growing upon it, upon some place where it did not interfere in the least with the creature's health, but merely with his running, or where it produced a blemish to his appearance; I do not believe anybody would object to a veterinary surgeon being called in to take out the tumour, and even if it were done without chloroform there would be no outcry, although it would be entirely for the pocket or the pride of the possessor that the operation would be performed.

4409. Probably it would be for the creature's advantage too?—It might not be so in the very least.

4410. Then you do not think that the relation between the man and the creature on which he is inflicting suffering for a remote purpose is in itself an evil; you think that it does not tend to harden the sympathies towards the lower animals?—I do not think it does at all if it is done in a right spirit.

4411. Can you give us any impression at all as to the first experiments you made; were they made under chloroform. I refer to your earliest investigations and experiments?—My earliest experiments were made on the frog, which I believe suffers so little that its sufferings scarcely need be considered. I daresay many here may have seen frogs shown at soirées for the purpose of exhibiting the circulation of the blood, the frog's body being in a bag and the toes tied out. If people really supposed that frogs were suffering as much as we should if we had our fingers tied with strings, we should not tolerate such an exhibition.

4412. Surely the question is not whether they suffer as much as we do; it might be conceded that they do not; but whether they suffer very much. Now we had evidence given us that frogs were kept in a jar till ulcers formed all round the eye from the unhealthy manner in which they had been kept, and that that was regarded as a matter of no moment whatever. Should you think that frogs with ulcers all round their eyes suffered nothing?—I really do not suppose that they suffer much as a matter of my own belief.

4413. That is very much matter of conjecture, I suppose?—No, I do not think it is at all. Take the case that I mentioned, for instance, of the salmon; I think that is absolute proof that the sensibility of the salmon's tongue and throat is nothing to compare with our own.

4414. Proof for the salmon but not for the frog?—But the salmon and the frog are very closely allied.

4415. Then you do not disapprove of the practice, which we find prevails in some schools, of not regarding the frog as a sensitive animal at all, and not administering anæsthetics during operations on it which would without them be painful?—I do not think it necessary to give anæsthetics to frogs, I must confess.

4416. Is that view at all caused by the difficulty of doing so, or is it simply that you think it does not suffer? Is there any considerable difficulty in giving ether?—There is another reason, that for one purpose for which the frog is very often used, demonstrating the circulation in the transparent web of the foot, if you give chloroform it is almost impossible to prevent the vapour of the chloroform from irritating the web and producing unnatural appearances.

4417. Does that apply to ether or injecting opium?—I have not tried ether myself, but I think it would probably have a similar effect.

4418. Or injecting opium?—Injecting opium might be as painful to the frog as the experiment that you were going to perform.

4419. There is no great pain attending the injection of opium into the human subject, is there?—No; but

Mr. J. Lister, M.B.

1 Nov. 1875.

the mere holding the frog in your warm hand is about as painful, probably, as any experiment that you would perform; to the cold-blooded animals it must be very painful, so far as they are capable of suffering.

4420. Then you would think the experiment which is given in the handbook before us, of raising the temperature of the frog to 35° or 40° Centigrade, a painful operation?—I should, relatively to the animal; but I do not believe the sufferings of the frog are deserving of serious consideration.

4421. Do you think that these kinds of experiments would be materially hampered by excluding the domestic animals, dogs, cats, and horses, from them? —I cannot imagine what object there would be in so doing.

4422. Only that evidence has been given to us that they are liable to a kind of hyper-æsthesia, a kind of suffering which is not the case at all with the rabbit or the non-domestic animals?—I confess I was not at all aware of the fact. I should have thought that in proportion the wild rabbit would suffer as much as the domesticated rabbit.

4423. But the rabbit itself is a creature which apparently gives very little sign of suffering of any kind, is it not?—The scream of a rabbit is not a pleasant thing to hear.

4424. Do you think that no distinction could be drawn between the different classes of the lower animals?—I think it would be a very undesirable thing to make any such limitation.

4425. (*Chairman.*) Your objection to legislation is founded mainly upon the opinion that no occasion has arisen for it yet in this country?—Certainly.

4426. That the operations are performed by persons who are perfectly competent, and who have a just sense, as you have expressed it, of their responsibility in the matter?—Yes, that is my distinct belief.

4427. If they were performed by other persons you think that the effect would be demoralising?—I think that if there were infliction of wanton cruelty that would be very demoralising.

4428. And if demoralising, then reasonably to be prevented by the interference of the legislature?—Undoubtedly.

4429. So that, to use your own phrase, your objection is that legislation is superfluous?—Yes.

4430. And when you express a sentiment that it might be in some way dishonouring to your profession, or a blot upon your profession, it would merely be the application to them of legislative precautions, for which you think they have given no provocation and no occasion?—Yes, as implying that there had been a necessity, which I did not believe existed.

4431. But if it should be the object of legislation to limit the power of performing any of these experiments to persons who are competent, and who have a proper sense of their responsibility, and only to exclude persons who are neither competent nor have such a sense of responsibility, perhaps that sentiment would be diminished?—If it could be done so as not to interfere with private investigation it might be unobjectionable.

4432. (*Sir J. B. Karslake.*) Do you yourself think that there is much difference in the pain that a dog suffers, as compared with that which a rabbit suffers under vivisection?—It is a point on which I cannot say that I have had much experience. I have several times operated on rabbits, but I have not operated much on dogs.

4433. Now, take a smaller animal than the rabbit; do you think there is any appreciable difference between the pain which a guinea pig would suffer and that which a rabbit would suffer under vivisection? —That I am not prepared to say.

4434. Do you think that there would be any appreciable difference in the pain that a wild fox suffers as compared with that which a dog suffers?—That I could not say; it is a subject to which I have not had my attention directed.

The witness withdrew.

Mr. George Richard Jesse called in and examined.

Mr. G. R. Jesse.

4435. (*Chairman.*) Are you in any profession?—I am retired from one.

4436. Will you have the kindness to tell us what it was?—Railway engineer.

4437. I think you are the Honorary Secretary of the Society for the Abolition of Vivisection?—Yes.

4438. Are you prepared to make a statement to this Commission on behalf of that society?—I am.

4439. Will you have the goodness to do so?—As already stated in a letter to this Commission, I appear at its request, not as a medical or scientific witness. My opinion as to vivisection has been arrived at by intimacy and close friendship with animals, the perusal of books written by vivisectors, and conversation with medical and other men, some of whom have witnessed the torture of animals for so termed scientific purposes. I am, on the part of the Society for the Abolition of Vivisection, prepared to amply and fully establish that the cruelties of vivisectors are not surpassed by any recorded in the history of mankind. I am prepared to establish that by furnishing extracts from the books written by those men themselves. I wish also to produce correspondence between some of those men and our association; moreover, extracts from the life of the late Dr. John Reid, of St. Andrews, and the life of Sir Astley Cooper. That these practices are becoming a moral ulcer, that they tend to demoralise mankind, and are by education vitiating the minds of the young, I wish to prove by the above and other works, and by reading extracts from Youatt's "Humanity to Brutes" (the famous veterinary surgeon), Dr. Elliotson's "Human Physiology," Lockhart's "Life of Sir Walter Scott," Drummond's "Rights of Animals," Dr. Ferrier's experiments, Dr. Bennett's experiments, and other books, including "Elementary Lessons in Physiology," "The Quarterly Review" for 1849, and also by publications of the Society for the Abolition of Vivisection. The Society for the Abolition of Vivisection, which contains many professional men amongst its members, peers, professors, officers in Her Majesty's service, and others, wishes to make known through this Commission to the people of England the deeds that have been done, and the opposition to the exposure of them it has met with from the unfair conduct of the "Times," "Standard," and the "Pall Mall Gazette."

4440. Can you put in a list of the members of the society?—Not at this moment.

4441. But you can send one to the secretary, I presume?—I could not quite pledge myself to that, because there are some who are members, and who would not like their names to be known.

4442. We only wish it to be understood by us correctly whether you are prepared to send in a list or not. I understand that you are not?—No, excuse me, that would be an erroneous impression. I am prepared to send in a list of the people who have given their names to the association, and which comprises by very far the greater number of its members. I am prepared to give that, but, of course, I cannot in honour give the names of men who wish their names to be private. If you like, I will apply to those men also.

4443. Will you have the goodness to proceed with your statement?—This is one of the first that comes to hand: The British Medical Journal, December 5th, 1874.—"Report of the Committee of the British "Medical Association to investigate the antagonism "of medicines, by John Hughes Bennett, M.D., "F.R.S.E., Chairman and Reporter." I should only take up time, I think, unnecessarily, by reading a

Mr. R. Jesse.

1 Nov. 1875.

great deal of this. I will come to the part, if you will allow me, which is most cogent to the point. "Experiment 473.—A male cat, weighing 4 lbs. 9 oz., "had six grains of theine injected under the skin of "the back. For five minutes nothing was observed. "At the end of this period it began to move back-"wards and forwards, and the excitement gradually "increased until the close of 15 minutes after the "administration of the drug, when it seemed to be "frantic. These fits of intense cerebral excitement "afterwards occurred at intervals of two or three "minutes; between them the animal lay quiet. It "appeared to be extremely susceptible to irritation. "A stick brought near it was immediately bitten. "Salivation became very profuse. Twelve minutes "after the dose had been given the cat had difficulty "in moving its posterior extremities. This difficulty "gradually passed into complete paraplegia. Thirty "minutes after it could not move the hinder part of "its body, but its senses were very acute. The ani-"mal noticed every movement made near it, and it "tried to bite. The paralysis gradually invaded the "fore extremities also, and the cat was unable to sit "up. It lay with its head slightly raised, but still "there was the same acuteness of the senses of hear-"ing and vision, and it was easily irritated. It "remained in this condition for an hour and a half, "when, after two very severe clonic spasms, it died. "The narrative of the above experiment indicates "intense cerebral excitement, associated with gradual "loss of the functions of the spinal cord." In regard to some experiments I have here, the Society has made extracts from them and printed them, and we have taken out the pith of them, as we consider; and it may save your time if I read what we printed. I can leave the document with you, so that you can verify it.

4444. Will you read it, if you please ?—It is No. 13 of our publications.

"Facts: 'Thine own mouth condemneth thee, and not I: Yea, thine own lips testify against thee.'—(Job, 15th ch., 5th and 6th v.) As it is often asserted that the practices of vivisectors are exaggerated, this Society brings forward more examples of them. 'Experimental Researches in Cerebral Physiology and Pathology,' by David Ferrier, M.A., M.D. (Edin.), M.R.C.P., Professor of Forensic Medicine, King's College, London, Assistant Physician to the West London Hospital. 'I have to thank Dr. Crichton Browne for kindly placing at my disposal the resources of the Pathological Laboratory of the West Riding Asylum, with a liberal supply of pigeons, fowls, guinea-pigs, rabbits, cats, and dogs, for the purposes of my research. The animals were extended on boards, the head and limbs first tied with cords, which were afterwards relaxed. The brain was exposed by sawing away part of the skull; the surface then extended by pincers, and electrical shocks or irritation given through copper wires applied to it. Concentrated chromic acid was also squirted into the brain through a small hole in the skull. Experiment I.—Medium-sized guinea-pig. Narcotised with chloroform, and the greater part of left hemisphere exposed. The animal was then placed on the floor, and watched. On recovery from stupor the body becomes curved from left to right, the head touching the tail. Active movements of the fore-legs are made, causing the animal to rotate round from left to right. Sometimes the animal makes violent struggles, and falls on its back. When the muscles of the right side are forcibly overcome, the state of pleurosthotonus returns on removal of the resistance. When placed on its right side the animal makes rapid movements with both fore and hind legs, as in running, but is unable to alter its position. When placed on its left side, it becomes curled from left to right, as before, and regains its feet. The pleurosthotonus and movements of the legs occasionally remit. Half an hour after the operation the animal is able to rest quietly on its feet, but with the head directed towards the tail, from left to right. The animal was then, 45 minutes after the operation, again narcotised, and submitted to electric stimulation, but death took place, probably from an overdose of chloroform, during the first application of the electrodes. Apparently the brain retained its excitability, but I discovered that the movements induced by stimulating different parts, and which were on the left side, were in reality due to conducted currents from too strong stimulation. The inferences I subsequently drew from the experiment were that the vital irritation, consequent on exposure of the hemisphere, acted on the muscles of the opposite side of the body through the corpus striatum, causing tetanic spasm and pleurosthotonus. The next experiments were undertaken with a view to ascertain,' &c. 'Several rabbits and cats were employed for this purpose,' &c. After detailing the above, Dr. David Ferrier proceeds to assert, 'It may be mentioned here, once for all, that before and throughout all the following experiments, ether or chloroform was administered.' The natural inference from this qualified statement must necessarily be that narcotics were not administered in all the previous experiments, whether in later ones they were always given or not, or given to render the creatures helpless. Whether the details now published invalidate the assertion of Dr. David Ferrier, whether intense and protracted agony was inflicted, may be estimated by these extracts from a 'mere preliminary instalment of a more extended and complete investigation,' as these experiments are termed by Dr. David Ferrier. The public may perhaps realise from them what is the significance of the phrase, experimenting on animals under anæsthetics. 'Experiment III.—The next experiment was made on a large strong cat. The skull was removed,' &c. 'The animal was only partially narcotised.' P. 68. 'My experiments, therefore, had to be extended over a great many different animals,' &c. 'With and without chloroform, the application of the electrodes apparently produced no effect, the animal remaining perfectly quiet. Occasionally, during application of stronger currents, the animal exhibited restlessness and uttered cries; but they did not indicate anything further than the usual restlessness and cries of guinea pigs when under experimentation.' P. 69. 'In addition also, the position of the animal's head, and its condition as to anæsthesia, seems to modify the results.' P. 77. 'In confirmation of these same results, I observe in my notes of experiments made on a rabbit, already alluded to (p. 36), that after about two thirds of the superior surface of the left hemisphere had been exposed, the animal ultimately recovered, but the whole of the exposed part become the seat of suppuration and fungus cerebri; so that the greater part of the cortical substance was rendered entirely functionless. During the five days intervening between the first operation and the second, which necessitated its death, the animal had apparently recovered perfectly without any distinct paralysis of the opposite side; but it had lost its natural sense of timidity, and regarded things which at other times would have frightened it, with a degree of stupid unconcern. It was also observed that though there was no distinct paralysis of the right side, the animal always had a tendency to run in a circle towards the right,' &c. The following are some of the scenes which ensued in regard to a cat. 'Experiment IV.—The greater part of the right hemisphere of a full-grown strong cat is exposed. The animal lies breathing quietly in the semi-narcotised condition,' &c. Observation 6. 'The animal exhibits signs of pain, screams, and kicks with both hind legs, especially the left.' Observation 12. 'The animal exhibited signs of pain, screamed, and kicked out with its left hind leg, at the same time turning its head round and looking behind in an astonished manner.' Observation 18. 'Repeated opening and closing the jaws. The tongue was seen often to be protruded and retracted.' Observation 19. 'While the temporo-sphenodial gyri were being further exposed, the animal bit angrily and gnawed its own legs. It

Mr. G. R. Jesse.

1 Nov. 1875.

did the same generally after irritation of the same parts.' Observation 20. 'In every case restlessness, opening of the mouth, and long continued cries as if of rage or pain.' Observation 21. 'The animal suddenly starts up, throws back its head, opens its eyes widely, lashes its tail, pants, screams, and spits as if in furious rage. This observation was several times repeated.' Observation 25. 'The excitability of the brain was now well nigh exhausted, and it entirely disappeared four hours after the commencement of the experiment, during which period the exploration was kept up uninterruptedly.' 'Experiment VI.—The left hemisphere of a lively mongrel cur' (sic) 'was to a great extent exposed before beginning the faradisation, and the other parts exposed in detail after the function of the previously exposed portions had been determined.' Observation 10. 'Electrodes to points, &c. Several applications elicited only cries as if in pain. As the animal was emitting cries also during the intervals of stimulation, it was thought that the cries of pain might not be the result of the stimulation, but their immediate intensification on the application of the electrodes seemed to be the direct result of irritation, &c. But the facts of the following experiments on dogs at first seem hardly in accordance with the idea of crossed action in the cerebral hemispheres. In two dogs, one of which has already been alluded to (p. 54), after failing to get further results from stimulation of the convolutions, I completely extirpated the right hemisphere. I give the particulars only of one case, though the two were somewhat similar. The first animal (p. 54) lived three days after the operation. In the second I removed the whole of the right hemisphere just anterior to the corpora quadrigemina. A few minutes after the operation the animal began to howl and bark, the movements of the jaws not having suffered the slightest degree of paralysis. The left sides and the limbs were distinctly weakened, while the right side and limbs seemed to retain their full power. The animal frequently turned its head to the right and struggled with its legs as if to rise and walk. The right fore and hind legs moved vigorously, but the left hind and fore legs were also frequently moved in a similar manner, though less powerfully. The movements of the left legs alternated with those of the right, but occasionally, when the right legs were held so as to get rid of their driving or leading action, the left fore and hind legs would be moved by themselves in the struggle to get free. Thinking that possibly the corpora quadrigemina might be concerned in these bilateral movements, I broke up the ganglia on the right side. But the phenomena remained much the same, though the animal seemed blinded, as it ran against furniture, walls, and jammed its head into impossible corners. It retained the power of opening both eyes, and of howling and barking in a very vigorous manner. Apparently it remained quite conscious, for, when called to, it would struggle to get up, and would sometimes regain its feet, and even succeed in walking a few steps, when it would fall over in a helpless manner. In these attempts the weakness of the left fore leg was very evident. An hour and a half after the operation, when in any way disturbed, it made struggles to get up. In these the hind legs moved alternately, the right certainly more actively, but the left fore leg was scarcely moved, though the right retained full power. The animal growled and barked very frequently. In order to determine whether the combined movements were conditioned by the voluntary impulse of the left hemisphere, I next proceeded, two hours after the removal of the right hemisphere, to expose the sigmoid gyrus of the superior external convolution of the left hemisphere. Having ascertained by electrisation that I could induce the usual movements of the right fore leg by stimulation of its centres here situated, I cut away the greater part of this gyrus, checking the hæmorrhage with cotton wool steeped in perchloride of iron. After this the animal ceased to struggle, and lay in whatever position it was placed. Pinching the toes caused reflex movements in all the four limbs, and at the same time the animal barked energetically and howled when pinched. Pinching of the tail especially caused the animal to bark. This condition continued for several hours, barking being always elicited and some reflex movements of the legs, but not to any great extent. The barking may also have been a reflex phenomenon; but from the fact that barking alone was sometimes induced without any marked reflex movements of the limbs I was rather inclined to attribute the phenomena to retention of consciousness and distinct sense of pain. Ultimately (five hours after the first operation) no barking was caused, but only reflex of the limbs and trunk when the legs or tail were pinched. The dog survived for eight hours after the removal of the hemisphere.' See the 'West Riding Lunatic Asylum Medical Reports,' edited by J. Crichton Browne, M.D., F.R.S.E. Vol. 3. London. Smith Elder & Co., 15, Waterloo Place, 1873. Price 8*s.* 6*d.* This and other papers on the subject may be purchased on application to the honorary secretary, at the rate of one page pamphlet, 2*s.* per 100; two page, 3*s.* per 100; four page, 4*s.* per 100; postage extra. The proceeds are given to the Society for the Abolition of Vivisection."

If you will allow me I will proceed to read now a correspondence between Professor Ferrier and the association.

"Vivisection. The Morning Post, London, Monday, 11th October 1875. We have been requested to publish the following correspondence, '16, Upper Berkeley Street, Portman Square, W., August 2, 1875. Sir, My attention has been drawn to an advertisment inserted by you in the Times of to-day, in which you profess to give extracts from a paper written by me in vol. 3 of the West Riding Lunatic Asylum Medical Reports, edited by Dr. Crichton Browne. With your views as to the justifiableness of the experiments there recorded I do not concern myself, being content to leave this question to the decision of a more competent and impartial tribunal than the society which you represent; but I have to request that when you quote me you will do so fairly. The first sentence of the paragraph from which you draw your account of the operative procedure, commences thus:—"In order to carry out the operations necessary for exposing the brain, and observing the effects of stimulation, I have simply *narcotised* the animal and extended it on a board," &c. (page 34). (The italics are not in the original.) In the opposite page (page 35) occurs this sentence: "It may be mentioned here once for all, that before and throughout all the following experiments, ether or chloroform was administered." You may draw what inference you please as to the purpose this narcosis was intended to serve; but when you suppress these important statements, and at the tail of your quotations convert them (italics excepted) into the following; "*it is stated* that chloroform and ether were given in *some* of the experiments," you do not succeed, whatever your intention may be, in conveying a truthful representation of the facts. I am, Sir, Your obedient Servant, David Ferrier. George R. Jesse, Esq., Henbury, Macclesfield."

"Henbury, Macclesfield, August 4th, 1875. Sir, Your letter dated the 2nd, and bearing London postmark of 3rd instant, arrived here this day. The expression of your unconcern for the views of this Society as to the justifiableness of the practices you term 'experiments' we estimate duly. And your professed opinion of the Society's competence and impartiality is what might be anticipated, as our endeavours are directed to bring those practices before the tribunal of public opinion. We believe you have been fairly quoted. If you think otherwise you can make your own statement in the newspapers. Your assertion that ether or chloroform was administered before and throughout all the experiments, is, we consider, invalidated by the details which accompany it. Will you explain why (if ether or chloroform was administered throughout 'Experiment 4 on a full-grown,

Mr. G. R. Jesse.

1 Nov. 1875.

strong cat') the creature exhibited 'signs of pain,' 'screamed,' 'turned its head round, and looked behind in an astonished manner,' 'bit angrily and gnawed its own legs,' uttered 'long continued cries as if of rage or pain,' 'lashed its tail,' 'panted,' 'screamed,' &c.? Was this an instance and proof of your assertion, 'It may be mentioned here, once for all, 'that before and throughout all the following experiments ether or chloroform was administered'? We pause for a reply. You also say in the first sentence detailing this experiment, 'the animal lies breathing quietly in the semi-narcotised condition.' How long did this 'semi' condition continue? Was it over ere you commenced giving electric shocks to the brain? Again at pp. 36 and 37, experiment 3, 'on another strong cat,' these words appear, 'the animal was only partially narcotised,' and a page 68 you have written, 'with and without chloroform.' Can you explain away the apparent inconsistencies of these statements of your own? The impression produced on the reader's mind, and stated in the 'Times' of the 2nd instant, is that to some of the unhappy creatures who fell into your power you gave ether or chloroform merely that they should be passive, helpless, and unable to struggle or defend themselves against you. Then they were fast bound, skull cut away, dura mater removed, eyeball extirpated, &c., after which, when the effect of the narcotic has passed away, you did that which drew forth screams and other manifestations of agony. Can you deny it? Our belief is that the statement as to giving ether or chloroform, whatever your intention may have been, does not convey the truth, but appears to palter in a double sense. The public may now, perhaps, realise what is the actual meaning of the phrase 'experimenting on animals under anæsthetics.' I am, Sir, your obedient servant, George R. Jesse, Honorary Secretary for the Abolition of Vivisection. Dr. David Ferrier, 16 Upper Berkeley Street, Portman Square, London, W."

"16, Upper Berkeley Street, Portman Square, W., August 9th, 1875. Sir, I am in receipt of your reply, dated 4th August, to mine of the 2nd, in which you ask me to explain certain 'apparent inconsistencies' between the phenomena I have described and the statement that the animals were narcotised. What to you may be inconsistencies do not appear so to those capable of interpreting the true significance of the facts. I would refer you to a letter on this subject by Dr. Crichton Browne to the editor of the 'Times' of August 4th, but personally decline to enter into discussions with you either publicly or in further correspondence. I have waited for your usual advertisement in Monday's 'Times,' and am glad to find it conspicuously absent. As it stood, it was an unfair distortion of the distinct statement which I again make, that anæsthetics were humanely administered before and throughout all the operations and experiments to which you allude. I am, Sir, your obedient servant, David Ferrier. George R. Jesse, Esq., Henbury, Macclesfield."

"Henbury, Macclesfield, September 2, 1875. Sir, We propose publishing the correspondence which has taken place between you and ourselves. As the question is a public one, we presume you can have no objection to this course. I am, Sir, your obedient servant, George R. Jesse, Hon. Secretary. Dr. David Ferrier, 16, Upper Berkeley Street, London, W."

To that letter we never had any reply. We sent it by two different channels.

Then the pamphlet containing that correspondence proceeds: "The following are the extracts alluded to." I have already read them to you from the other paper, and need not read them over again. Then there is this note, "Dr. David Ferrier commenced this correspondence (possibly in the hope of being able to use it to his advantage), but was prompt to end it. He evades explanation of the apparent inconsistencies of his own statements. His mere assertions will hardly satisfy public opinion for the absence of evidence. It is remarkable that while Dr. David Ferrier insinuates we are incapable of interpreting the true signifiacance of the facts, and refers us to his colleague, Dr. J. Crichton Browne, the latter, in the Times of August 4th, gives us credit for being well informed as to the 'phenomena' these experiments drew forth." The letter I now wish to read is the one to which he alludes from Dr. Crichton Browne. The answer to that I also now have in my hands, but the Times would not allow it to appear. There is no doubt that they received it; we sent it by an agent, who saw Mr. Knight, of the Times, and we also wrote again; and we contemplated at one time proceedings against the Times for allowing Dr. Crichton Browne's letter to appear, and not our reply to it. We wrote again to request that they would insert the reply, but got no answer. We did not take proceedings, because we were advised that we were not likely to make much of it. This is the letter which appeared in the Times from Dr. Crichton Browne:—

"To the Editor of the Times.—Sir, An advertisement which appeared in your columns yesterday, under the authority of the Society for the Abolition of Vivisection, contains statements which are skilfully misleading, and which call for immediate correction. After giving an inaccurate description of the mode of experiment adopted by Professor Ferrier in his important researches into the functions of the brain, and after quoting a few of his observations, adroitly selected, because to the non-professional reader they may seem to justify the unwarrantable conclusion that 'intense and protracted agony' was inflicted during their progress; the advertisement proceeds to say 'it is stated that chloroform and ether were given in some of these experiments, but it appears to have been done with the view of rendering the animals helpless.' It will, I think, scarcely be credited that this is the version which the Society for the Abolition of Vivisection thinks proper to give of Professor Ferrier's distinct intimation, made at the outset of the paper in the 'West Riding Asylum Medical Reports,' from which the observations were quoted. 'It may be here mentioned, once for all, that before and throughout all the following experiments ether or chloroform was administered.' Everyone able to understand the meaning and purpose of Professor Ferrier's experiments will at once perceive that it was essential to their success that the animals employed in them should be unconscious and incapable of feeling pain, or of making any voluntary effort. The movements and cries produced by the faradization of the brain were not expressive of suffering, but simply of the stimulation of a motor-centre, and the 'intense and protracted agony' of the animals exhibiting these signs of pain was not greater than a pianoforte when its keys are struck. Similar signs of pain may be witnessed in an animal without a brain, or in the deepest state of anæsthesia. It is an elementary truth in physiology that the brain tissue itself is absolutely insensitive, and may be irritated or sliced away without even discomfort being occasioned. All this must have been well known to those who concocted the advertisement referred to, and yet they have not hesitated to deceive the public by representing mere automatic movements as indications of 'intense and protracted agony.' To such base practices may not ill-judged enthusiasm or a thirst for subscriptions reduce even a benevolent society! I am, Sir, your obedient servant, J. Crichton Browne, West Riding Asylum, Wakefield, August 3."

This is the answer which we sent to the Times and which it would not insert:—

"Vivisection.—To the Editor of the Times.—Sir, 'To such base practices may not ill-judged enthusiasm or a thirst for subscriptions reduce even a benevolent society!' You have thought fit to give place to the above language in your issue of the 4th instant; your sense of justice will allow the reply. Professor Ferrier's 'experiments' were brought to our notice by a Fellow of the Royal Society, who expressed his disapprobation both as to the absence of scientific

Mr. G. R. Jesse

1 Nov. 1875.

perspicacity and common humanity, which, in his opinion, characterised them. Mr. J. Crichton Browne asserts the statements of the Society for the Abolition of Vivisection are 'skilfully misleading,' and the quoted observations 'adroitly selected.' He compliments our ability at the cost of our veracity. But our quotations from Dr. Ferrier's 'experiments' were literal extracts taken in regular succession from one on a cat. Dr. Ferrier's assertion that ether or chloroform was administered before and 'throughout all' his 'experiments' is, we believe, invalidated by the details which accompany it. If ether or chloroform was administered throughout 'experiment IV.' on a full grown strong cat, and (as Mr. J. Crichton Browne's credulity permits him to affirm, though it is what he cannot possibly know) the creatures felt no more than a pianoforte, how was it the animal gave evidence of astonishment, anger, rage, and pain? How was it the creature uttered long continued cries, screamed, and gnawed his own legs, &c.? The last a strong manifestation of agony. As the animal expressed sentiments of the mind, was it not sensible? Can stimulations of 'motor centres' give rise to emotions of the mind corresponding therewith? Even, if so, has agony a 'motor centre'? We are told these manifestations of agony arose from 'simply the stimulation of a motor centre'? Why then when other 'motor centres' were 'stimulated' did not the cat evince signs of love and other feelings? Why did it not purr, show pleasure, and attempt to caress the professor instead of displaying the most marked indications of astonishment, anger, rage? At experiment III., on another 'strong cat,' these words appear, 'The animal was only partially narcotised,' and on another page we find the words 'with and without chloroform.' In one 'experiment' the right hemisphere was removed from a dog and he lived three days after the mutilation. In another 'the whole of the right hemisphere was removed just anterior to the corpora quadrigemina.' The animal, a few minutes after, howled and barked, &c. 'Apparently it remained quite conscious, for when called to it would struggle to get up.' From the fact that barking alone was sometimes induced without any marked reflex movements of the limbs, I was rather inclined to attribute the 'phenomena to retention of consciousness and distinct sense of pain.' 'The dog survived for eight hours after the removal of the hemisphere.' Mr. J. Crichton Browne asserts the insensibility of the brain. Can he be sure that sensation may not be conveyed by it? He will hardly say that the dura mater is otherwise than excessively sensitive. In conclusion, I ask, why does not Professor Ferrier stand forth himself publicly and defend his own deeds. As to Mr. J. Crichton Browne, who comes in his place, the intemperance of his language is not indicative of the justice of his cause. We trust he will live to feel ashamed of the aspersions he has cast. I am, Sir, Your obedient servant, George R. Jesse, Honorary Secretary of the Society for the Abolition of Vivisection. Henbury, Macclesfield, Cheshire. 7th August 1875. P.S.—There are different reasons for giving chloroform. It is not always administered so as to produce insensibility. Sometimes merely enough may be exhibited to narcotise the public mind, and enable the 'experimenter' to make merciful statements. It is often given only to secure entire helplessness on the part of the patient. G. R. J."

The next paper is the following:—

"Facts. As it is often asserted the cruelties of vivisection are exaggerated, this society brings forward examples of them. Since Majendie's time (who did much to inoculate this nation with the contagious virus of the moral ulcer) there is evidence to prove they have largely increased in number. House of Commons, February 24, 1825. 'Hansard, N. S., Vol. 12, p. 658. Mr. Martin of Galway. There was a Frenchman . . . . of the heart and viscera.' (Great disgust at the statement of this cruel experiment was manifested by the House.) House of Commons, March 11th, 1825. Mr. Martin replied.—'One word as to Professor Majendie. . . . . made it in that House.' 'During the first winter in which I attended . . . . can conscientiously vouch.'—'The Rights of Animals, &c., by William H. Drummund, D.D., M.R.,I.A., London, &c. 1838.'"

"The late Dr. John Reid, Fellow of the Royal College of Physicians of Edinburgh, and Professor in the University of St Andrew's, repented of the tortures he had perpetrated upon the defenceless. Dr. Reid was cut off in the prime of life by cancer at the roof of the tongue, and he repeatedly said to his medical attendants and the members of his family, in allusion to the seat of his long continued agonies, being the same nerves on which he had made so many experiments, 'This is a judgment on me for the sufferings which I inflicted on animals.' How terrible those torments must have been may be estimated by the awful retribution recorded in his life. The grave suddenly yawned at his feet, his countenance cheerless and wan, was gloomy and desponding almost to despair, opium and chloroform daily taken to alleviate his anguish, sleepless nights of unquenchable agony, slow starvation, bodily exhaustion, demon voices reiterating blasphemies, and hoarsely whispering 'curse God and die.' So lowered were his powerful frame and natural energy, that on meeting accidentally his old companion (Mr. Fergusson) in the street, Dr. Reid burst into tears. This physiologist referred to his past life as nothing but a long and dark array of sins and follies. The sufferings he inflicted were not merely incidental to dissection, equivalent to severe surgical operations, but in many of the experiments recorded were deliberately inflicted. It was considered essential that the animals should be left free to exhibit all the pain they felt, and should be expressly subjected to torture. He confessed to having thought much of scientific fame in his labours, and it would be untrue to say the alleviation of human suffering was the motive always before him when he inflicted pain on the lower animals. Dr. John Reed departed this life the 30th July 1849. *See* Life of Dr. John Reid, by George Wilson, M.D. Edinburgh, Sutherland and Knox. London, Simpkin, Marshall, & Co., 1852. Also, Physiological, Pathological, and Anatomical Researches, by John Reid, M.D., &c. Edinburgh, Sutherland and Knox. London, Simpkin, Marshall, & Co., and Samuel Highley, 1848.'"

As this has been called in question several times, there has been a great deal of correspondence in the Scotsman, where we have had to meet a good many antagonists; but I think, in the opinion of any candid and clear sighted man, we have most completely overthrown them, and substantiated every word of it. In fact, there is Wilson's book for anybody to go to. We go on to say, in our pamphlet,—

"In proof that such nameless and demoralising deeds are not only perpetrated, but even becoming educational and systematic in the kingdom, thereby tainting the minds of the rising generation of young men devoted to the profession of medicine, and familiarizing them to scenes of cruelty and cries of agony, it is of great moment to state that in a pamphlet on Edinburgh University extension, and which contains notes on plans, submitted after confidential intercourse and discussion by an architect in 1874, occurs the following:—Page 13. 'I have placed physiology at the south-west corner, because it is desirable to place this department in such a position that it cannot be overlooked, and also where good south and north light can be had. . . . On the ground floor is a room (30 ft. 6 in. by 9 ft.) for physiological experiments on animals. . . . . Another reason I have for placing the physiological department here is, that there is good space for keeping animals, and plenty of south light to preserve them in health. . . . Good accommodation can also be had for keeping the animals belonging to the pathological department. Edinburgh, 30th December, 1874.' Anderson is the name of the architect. We did not put his name in the pamphlet, because he only acted in his professional capacity. "A professor,

Mr. G. R. Jesse.

1 Nov. 1875.

of Edinburgh University, has recently stated, 'For the discovery of new truth, or for the purpose of testing the truth of statements not yet coroborated, experiments without the use of narcotics are, if necessary, had recourse to on rabbits, guinea pigs, or dogs, but those are never given as demonstrations to students. Such experiments are performed in private by my assistant or by myself, and, it may be, some fully qualified person working under our immediate superintendence.' William Rutherford, Professor of the Institutes of Medicine (Physiology), University of Edinburgh, July 2, 1875. [See 'The Scotsman,' 3rd and 10th July 1875.]"

I propose now to refer to the life of Dr. John Reid, by Dr. George Wilson, page 124. "I am not anxious . . . . at present they are."

4445. What is the date of that?—This is the second edition, dated 1852.

"A premium as . . . . ethics it is one."

4446. Are there other passages in that book to which you desire to draw our attention?—This is the only remaining one, and it will be found at page 130:—

"We are thus taught . . . . committed to our care."

The next book to which I have to refer is "Lessons "in Elementary Physiology, by Thomas H. Huxley, "LL.D., F.R.S." 1874. "Preface to the first "edition. The following 'Lessons in Elementary "Physiology' are primarily intended to serve the "purpose of a text-book for teachers and learners in "boys' and girls' schools." In the preface to the second edition I find, "As the majority of the "readers of these lessons will assuredly have no "opportunity of studying anatomy or physiology upon "the human subject, these remarks may seem dis"couraging. But they are not so in reality. For "the purpose of acquiring a practical, though ele"mentary, acquaintance with physiological anatomy "and histology, the organs and tissues of the com"monest domestic animals afford ample materials." Then there are these directions at page 255: "If "when the cord is cut across in an animal the cut "end of the portion below the division, or away from "the brain, be irritated, violent movements of all the "muscles supplied by nerves given off from the "lower part of the cord take place, but there is no "sensation. On the other hand, if that part of the "cord which is still connected with the brain, or "better, if any afferent nerve connected with that "part of the cord be irritated, great pain ensues, as is "shown by the movements of the animal, but in these "movements the muscles supplied by nerves coming "from the spinal cord below the cut take no part; "they remain perfectly quiet." At page 252,—"If "the trunk of a spinal nerve be irritated in any way, "as by pinching, cutting, galvanising, or applying a "hot body, two things happen. In the first place, "all the muscles to which filaments of this nerve "are distributed, contract; in the second, acute pain "is felt, and the pain is referred to that part of the "skin to which fibres of the nerve are distributed. "In other words, the effect of irritating the trunk "of a nerve is the same as that of irritating its "component fibres at their terminations." At page 52,—"That this is the real state of the case may be "proved experimentally upon rabbits. These ani"mals may be made to blush artificially. If in a "rabbit the sympathetic nerve, which sends branches "to the vessels of the head, is cut, the ear of the "rabbit, which is covered by so delicate an integu"ment that the changes in its vessels can be readily "perceived at once, blushes. That is to say, the "vessels dilate, fill with blood, and the ear becomes "red and hot. The reason of this is that when the "sympathetic is cut, the nervous stimulus, which is "ordinarily sent along its branches, is interrupted, "and the muscles of the small vessels, which were "slightly contracted, become altogether relaxed. "And now it is quite possible to produce pallor and "cold in the rabbit's ear. To do this, it is only "necessary to irritate the cut end of the sympathetic, "which remains connected with the vessels. The "nerve then becomes excited, so that the muscular "fibres of the vessels are thrown into a violent state "of contraction, which diminishes their calibre so "much that the blood can hardly make its way "through them. Consequently, the ear becomes "pale and cold." I might read other passages of the kind in this work, but as they are very much indeed to the same purpose, I shall not take up the time of the Royal Commission unnecessarily; but I wish to make that remark to go in evidence, that there are other passages of the kind. The next book to which I wish to refer is "The Rights of Animals, "and Man's Obligation to treat them with Humanity, "by William H. Drummond, D.D., M.R.I.A., and "Honorary Member of the Belfast Natural History "Society."

4447. Is he living?—That I do not know. The date of this book is 1838. At page 163 it says:—

"Innumerable experiments have . . . . suffering entirely obliterated."

Then the next book to which I would refer is a book entitled "Vivisection. Is it necessary or justifiable? Being two prize essays published by the Royal Society for the Prevention of Cruelty to Animals," and published in London by Robert Hardwicke, 192, Piccadilly, in the year 1866. What I wish to refer to is an extract which it contains from a work written by Mr. J. Burn Murdoch, of Gartincaber, Edinburgh, in 1846, entitled, "An Account of a Visit to the Veterinary School of Alfort, in 1844."

4448. Do you wish to refer us to particular passages in that book, as showing the evils of the system of vivisection?—Yes.

4449. Will you be so good as to give us the references to them?—I will furnish them afterwards. My object in referring you especially to that passage headed "A visit to Alfort" is this; it is simply harrowing in its details, and he being a veterinary surgeon, of course he is competent to speak, and I expect he is a very good authority; and the thing almost culminates in those horrors. Our object in bringing that forward is to show what length these things not only can go to, but have gone to, and that what has occurred in France may occur here. I am now going to read a very few lines out of another work, and my object is to show how the thing is spreading; that it is not confined merely to laboratories and hospitals, but is done in lodgings and so on; in fact, that it is permeating general society. It is called "Me"dical Students of the period. A few words in "defence of those much maligned people; with "digressions on various topics of public interest "connected with medical science, by R. Temple "Wright, M.D., late scholar of King's College, "London," and it is published by William Blackwood and Sons, Edinburgh and London, 1867.

4450. Is Mr. Wright living?—I do not know; I have not the honour of his acquaintance.

4451. You refer us to that book as showing that in your opinion evidence is obtainable of the spread of the system?—Yes.

4452. What page do you particularly direct our attention to?—Page 137 and page 138.

4453. (*Lord Winmarleigh.*) Does that book contain opinions expressed by people to the society, or are they facts?—I do not know whether they are facts or not. The writer gives them here in this book as facts. I want to show what some of these young fellows do in their lodgings when they meet in an evening.

4454. (*Chairman.*) Have you read the book yourself?—No; I have read the passages I particularly refer to.

4455. Are you acquainted with the writer?—Not at all.

The witness withdrew.

Adjourned to to-morrow at two o'clock.

Tuesday, 2nd November 1875.

PRESENT :

THE RIGHT HON. VISCOUNT CARDWELL IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

ROBERT MCDONNELL, M.D., called in and examined.

R. McDonnell, M.D.

2 Nov. 1875.

4456. (*Chairman.*) You are surgeon to Steevens' Hospital in Dublin ?—Yes.

4457. And a Fellow of the Royal Society ?—Yes.

4458. And a surgeon in practice in Dublin ?—Yes.

4459. Now have you paid particular attention to the subject of our inquiry ?—I have been for many years a teacher of physiology,—Lecturer on Anatomy and Physiology.

4460. What is the general feeling in Ireland about experiments upon living animals ?—I do not think that there exists in our schools any abuse that has called forth any very strong feeling on the subject.

4461. But we have been told by one of our former witnesses that there is a very strong feeling upon the subject in educated society in Dublin; do you believe that to be the case ?—Yes, no doubt.

4462. And is that same feeling that is a sentiment of humanity, strongly shared by the medical profession in Dublin ?—I think it is.

4463. And by the students ?—I think it is.

4464. Do you believe that there has ever been in Ireland any reckless experimenting by students ?—No, certainly not; I never knew of it.

4465. Suppose that you were to introduce living animals for experiments for demonstration to students, and that you did not propose to use anæsthetics, what do you think would be the feeling of the students ?—Unless you were able to give some good reason for doing away with the anæsthetics I am sure that our students would not tolerate it; the public opinion of our students, who are intelligent and kindly young men, would be strongly against it.

4466. Now of such experiments as are useful for demonstration, may all be done under anæsthesia ?—The vast majority, I should not say all.

4467. But very nearly all ?—Yes, very nearly all.

4468. Now speaking both of demonstration and of original research, may most of the experiments be performed while the animal is unconscious ?—I should say the vast majority.

4469. And of those that remain may a considerable part be so performed that the most painful portion of the experiment shall be under anæsthetics ?—I should say clearly yes.

4470. Then with regard to those which still remain, are they experiments upon sensation ?—Yes, they would be experiments that must be excluded from anæsthetics.

4471. Are they numerous or rare ?—They are rare.

4472. When a fact has been already established, such, for instance, as the facts which were established by Sir Charles Bell, would you propose that there should be a repetition of such experiments ?—No, certainly not, when once thoroughly established; but while *sub judice* I think the case is different.

4473. But where a fact has been sufficiently established, you would hold that it is very wrong to repeat it, if of that kind where the animal must necessarily feel pain ?—Yes.

4474. Then of this small portion of the experiments that remain, namely, where sensation is the object of the experiment, and where the fact to be established is a new one, do you contemplate that protracted agony would be one of the consequences ?—No, certainly not; the animal would be destroyed immediately after the experiment.

4475. Now have you turned your attention to the subject of legislation ?—I have thought about it, but I confess I see immense difficulties in practical legislation. I cannot say that my thoughts have taken any definite form. I see very great difficulties in the way.

4476. Do you think that the position of the physiologist would be in any way improved by legislation ?—I do; as a physiologist I should like some legislation to save the physiologist from the outcry that has been raised by mis-statements and exaggerations. I think it would give public confidence if some means could be devised of getting at the truth without interfering with the progress of science; I think it would be desirable for the physiologist to have the protection which would arise from disarming the suspicions of the public.

4477. Have you at all turned your attention to the line which such legislation might take ?—I cast my eye over the Bills which were brought forward last year, but I cannot say that I thought that either of the two Bills which I read would very well meet the case.

4478. Have you turned your attention at all to another idea which has been suggested, that of inspection ?—Yes, I have; but here again I confess I found very great difficulties; a difficulty between its being a mere sham which would not give the public the necessary confidence, and its being an inspection of a kind which would really interfere with the progress of science.

4479. What I have understood you then to say generally is this: that you would look with favour upon legislation as a protection to those who are qualified to instruct in physiology, but that you have not elaborated in your own mind any scheme by which such legislation could be rendered effectual for its purpose, without being productive of interference with what you consider necessary; is that the state of the case ?—Yes.

4480. Now you have spoken of the students in Ireland as being impressed with sentiments of humanity. Do you think that there is any tendency in such experiments as are performed before them to demoralize them ?—No, I think not. It acts upon the student just as an operation upon the human being. If he is in contact with a teacher who has a noble object, and who impresses his class with the idea that he has a noble object in view, it has a humanizing and not a brutalizing effect.

4481. Do I rightly understand you to mean that it is the spirit of the teacher which causes the seeing of experiments to be demoralizing or the reverse ?—In some degree it is the spirit of the teacher; but I think it is exactly as Bishop Butler long since pointed out; if the mind is under the active idea that great good is to result from it, it has a humanizing and improving effect; if it is a passive spectacle of horror like a bull fight or an execution, it is demoralizing. The active is beneficial, the passive witnessing of suffering is demoralizing.

4482. Then it is impossible from your point of view to lay down a positive line of demarcation on the subject, except that the motives in view and the spirit in which the experiment is conducted, render it either demoralizing or otherwise ?—Yes.

4483. If then it is in the hands of proper and humane persons you think it not to be demoralizing; but if it were to be in the hands of persons of an opposite character you would think it demoralizing ?—That is precisely my view.

4484. (*Lord Winmarleigh.*) Do you know of any other places in Ireland besides that in which you oper-

R. McDonnell, M.D.

2 Nov. 1875.

ate, in which experiments are made upon living animals?—I am acquainted with all the schools in Ireland more or less, and in none of our schools can it be said that experiment on living animals is carried on as a means of instruction in the lecture theatre.

4485. But by way of experiments for research I mean?—I am one of the few physiologists in Ireland who has done much in the way of experimental physiology, and my principal researches have been scientific researches at which I permitted my pupils to be present; but in none of the schools in Ireland is there any actual course of experimental physiology given.

4486. You said that in a very small minority of cases experiments cannot be made under anæsthetics?—Yes.

4487. Is it your opinion that even in that small number of cases which you say form the exceptions, the pain could be diminished by soporifics or any other means?—No, certainly not. In this particular class of cases the experiments are on sensation; the pain could not be avoided therefore in that particular class of cases.

4488. Are there any of those which you have practised yourself in which there has been prolonged pain?—No, not prolonged pain, but unavoidable pain. I have repeated at the time that they were quite new and *sub judice* the researches of Dr. Brown-Séquard upon the spinal cord of animals. In those cases I believe it is unavoidable to have suffering, but the animals were instantly destroyed.

4489. In your own experience, what is about the longest period for which pain has been suffered by the animal?—That is a question very difficult to answer, because of course there are some experiments in which it is necessary to keep the animal alive. Although you may save it the pain at the time of the operation, it is necessary to keep it alive in order to see the result. In such cases as that all pain would be saved at the time of the operation, and you would merely have the pain which a wound might cause.

4490. (*Chairman.*) You are not now speaking of experiments to test sensation?—No. I may say that I would divide experiments into three classes. First, those in which anæsthetics can be given, and in which immediately, before the influence of the anæsthetic passes away, the animal is destroyed; in which experiments, therefore, there is absolutely no suffering. Secondly, those in which the anæsthetic may be perfectly well given, but in which it is necessary to watch the result, and the animal, therefore, must be permitted to live for a period in order to ascertain the result; in that case the animal will be saved entirely the pain of the operation; but the subsequent and slighter pain of the smarting, and so on, which may occur afterwards, is, I think, unavoidable; but it is comparatively but slight. Thirdly, you have the very small class of cases in which, inasmuch as the physiologist has to test sensibility, it is a necessary part of the research that the animal shall be able to feel; there we cannot use anæsthetics, but in those cases the animal is immediately destroyed. I here refer only to experiments attended by cutting operations. The important class of experiments dealing with the action of drugs, the nutritive qualities of food, the development of entozoa, &c., would not come under these heads.

4491. (*Lord Winmarleigh.*) Do you think those experiments of essential importance for medical or other treatment of human beings?—I think they are among the very most important of the last quarter of a century.

4492. Could you mention one or two which you consider of most importance to the human race?—I should say that Dr. Brown-Séquard's discoveries, with regard to the artificial production of epilepsy in animals, would probably be looked upon as one of the most important.

4493. That has been discovered through these means, has it?—Yes.

4494. And could that have been discovered through any treatment of the human body?—No, clearly not.

4495. Would you mention another?—I would group together all his discoveries with regard to the conducting channels in the spinal cord.

4496. And those experiments could not have been made upon human bodies?—No, clearly not.

4497. You are quite clear of that?—Yes.

4498. And if anybody stated here that they could be so made, you would think that a mistake?—Yes.

4499. (*Sir J. B. Karslake.*) Do I rightly understand that you have a class of students to whom you lecture on subjects connected with physiology?—I was for many years a lecturer; I am not now. I am one of the Examiners in the College of Surgeons now, and it is not compatible with that position that I should be a lecturer.

4500. When did you cease to be a lecturer to a class of students?—About two years ago.

4501. And for how many years had you been lecturer?—Nearly 20 years.

4502. In the course of your lectures you never exhibited any experiments upon living animals?—Not in my systematic course; but in some cases where I was of necessity myself repeating experiments, I gave my pupils the opportunity of seeing them.

4503. But that was rather as a matter of favour than as any part of the systematic course?—Yes.

4504. In giving the students that opportunity, did you do so because you thought it would perfect their education in physiological subjects?—The class that attended me at that time were some of them young medical men who had already passed their examination, and who came from the same desire that I had myself to ascertain exactly the results. It was a new subject; it was one completely novel in the medical world at the time. I was repeating the experiments with a view to ascertain whether they were true or not, to verify them; and I gave some of my former pupils and the most intelligent of the students the opportunity of being present at these lectures. Some of my hearers at that time were already qualified as medical men.

4505. Have you formed any opinion yourself as to whether the education of a student can be satisfactorily completed without demonstrations of this description?—It is very difficult to answer in general terms such a question as that, because we must understand what is meant by "experiments" first. Take such an experiment as showing the circulation in the frog's web; some people might cavil at that as an experiment on an animal; or, for instance, rendering a tadpole insensible in order to place it under a microscope. Those are things which you could not educate a pupil, I think, without showing him.

4506. You think that there are some things in which you give a certain amount of pain to animals which it is necessary to show to students?—Certainly; I do not think you could give a medical man a proper education without it.

4507. (*Mr. Erichsen.*) Is there pain in those experiments?—I should say almost none. That is the difficulty, however, where to draw the line. There can be no pain that a reasonable person would object to I think in placing a frog's web under the microscope; but then some people are so sensitive; I have heard persons object even to that.

4508. (*Sir J. B. Karslake.*) What I was rather wishing to get at was your view of this subject, whether there are matters which cannot be fully understood by students, without the assistance of these experiments, and which it is necessary for them to understand?—I think there are some which it is necessary to show to students.

4509. Is there any particular class of animals upon which you generally make your experiments, or do you use dogs, and cats, and rabbits, and frogs like most other gentlemen performing these experiments?—We all use the same; but as a matter of fact it is hardly done with us at all; the experimenting upon

R. McDonnell, M.D.

2 Nov. 1875.

animals as a systematic part of the training is very little done with us.

4510. And even for the purpose of physiological research is the number of animals that you sacrifice small?—Very few.

4511. (*Chairman.*) I suppose you consider that in Ireland this mode of research and of teaching is quite in its infancy, do not you?—I do not know that. It has been carried on for a good long time for purposes of research, but I think it is done with a great attention to humanity.

4512. (*Sir J. B. Karslake.*) You said just now that you did not think there was any reckless conduct on the part of students or young medical men in Ireland in making these experiments?—I need not say "no reckless conduct," on the part of the students for there is no conduct at all; they do not do it.

4513. As far as you know, excepting your own laboratory, do the medical students or young medical men enter upon these experiments at all in Ireland?—In my 20 years experience I never knew a medical student think of original research or of anything else except his final examination.

4514. Or a young medical man?—Young medical men after they pass their examination, if they are really earnest in their desire to advance the science of medicine and surgery, must begin sometime to do it. I did it myself when I was young.

4515. Did you do it in your own private study?—I did it in the laboratory of the school with which I was connected.

4516. It was done more or less, I suppose, under the supervision of the authorities of the school?—No, but with their knowledge and cognizance; they might have been present, but they had perfect confidence that I would not abuse the trust reposed in me.

4517. So far as others do the same thing in the present day, do they do it, do you think, in their private houses or in laboratories?—I think, from considerations of convenience, it may be said always to be done in laboratories. I have made some experiments in my own house, but very rarely.

4518. (*Mr. Huxley.*) I think we may gather from what you have said, that if you were desirous of carrying on a series of experiments, if the alternative in any case were offered to you or presented itself in performing a painful experiment of using anæsthetics or not using them, you would certainly use them?—Certainly, always.

4519. You have known a good many physiologists both of your own country and of these islands?—And America.

4520. Did you ever know any exception to that rule?—Never.

4521. You never knew a man who, if the opportunity offered itself, would put an animal to pain rather than sacrifice a little of his own convenience?—Never. I myself, and I believe all of us, would shrink from that with the greatest possible repugnance.

4522. I understood you to say that, so far as your knowledge of Ireland is concerned (and it seems to be extensive), you do not think that there are any abuses existing which would form a ground for legislation?—I should say certainly not.

4523. And if you desire legislation at all it is rather as a matter of protection to physiologists?—Yes.

4524. I think that when you began to teach 20 years ago, I may say that the modes of teaching physiology were not so thorough as they are now?—By no means.

4525. In fact, I might say that of most branches of science, for example chemistry, was not then taught in the thorough way it is now?—No; practical teaching of all kinds has been developed immensely.

4526. I suppose that when you were a student 20 or 25 years ago, it was not, I will not say possible, but at any rate it was not easy to obtain practical teaching in a chemical laboratory?—It was impossible you may say.

4527. And therefore, in asking you about your practice when you began to teach, and in suggesting that there are some things that you might think it desirable to do now which you would not do then, of course I am not for a moment throwing any doubt upon the teaching being up to the level of its time; but I presume at the present day, if you were now teaching physiology, there are certain things which you would imagine no student could properly understand unless he had had them put before him in a visible shape; take, for example, Weber's experiment on the pneumo-gastric nerve; I presume you would like a student to see that?—If I were lecturing on physiology now, I would consider it my bounden duty to repeat such an experiment as that each succeeding year. It can be done absolutely without pain, and it is an experiment of so much importance that I would look upon it as my bounden duty as a man desirous of promoting the interests of my fellow creatures, to repeat that every year.

4528. And on the ground that no man by mere description could form any adequate conception of the very striking phenomena which are brought out by that experiment?—Precisely.

4529. Various suggestions have been made by witnesses here as to the mode in which experimentation should be regulated. Now one of these suggestions is that no such experimentation should take place except in a theatre or large open room provided with a gallery, to which the public are to be admitted, a certain proportion of the public being persons who are not students of physiology; and it has been suggested that that would be an efficient check upon the supposed tendencies of physiologists to carelessness and cruelty. What would you think of that arrangement as a practical experimentor?—I should not have the slightest objection to it from one point of view, but it would be perfectly ridiculous in another. It would be no check whatever, because you could not prevent physiologists who did object to making experiments in public from making them in private; and they would make them in private.

4530. Do you think, supposing that a man were obliged to carry on delicate and difficult researches under those circumstances, that his attention to what he was about would be at all favoured by the fact of there being a number of persons looking on?—Many experiments could not be carried on in such a place; they are too delicate. If you are to use delicate instruments, as galvanometers for instance, you cannot have a crowd of people about.

4531. And would it not be another difficulty that persons not instructed in these matters (and on the hypothesis a certain proportion would be of that class) might form a most entirely erroneous judgment as to whether pain was inflicted or not?—Yes; no doubt. An ordinary observer cannot believe that reflex movements in a frog's leg are not evidence of pain, although you may have nothing there but the part below the middle of the body. I may mention that I recollect once myself being assailed for showing the pulsations of a heart entirely removed from the body of a frog, so hard is it for some persons to believe that there is not evidence of pain in that kind of movement, that kind of lurking vitality, which hangs about the heart of one of the lower animals, just as a rose will blossom in water after being pulled from the stem. Many people cannot conceive that that is not cruel; but in reality there is no cruelty there.

4532. If I may refer to an experiment with which you are very familiar made on a decapitated frog, in which a drop of acetic acid is put on the region of the loins, you are aware that the frog takes up a leg on one side and rubs the place?—Yes.

4533. And if that leg is held he will take up a leg on the other side and rub it, at great inconvenience. Now, I suppose it would be impossible to persuade anybody who did not understand these things that the frog in that case did not feel?—Yes; unless they saw the same thing done by a man whose spinal marrow was injured by an accident. The only way to

R. McDonnell, M.D.

2 Nov. 1875.

convince them that it does not feel is to make a human being do the same, who assures you that he cannot feel. I have seen a case in which, on the surgeon attempting the introduction of the instrument, a patient unable to feel, has shaken his hand, and put it down like this (*describing it*) although he could not tell, if his eyes were shut, that anything was being done to him; therefore, when we meet with a case of that kind in a human being it convinces us that the frog does the same without any consciousness.

4534. (*Mr. Erichsen.*) And the condition of the human being in the case supposed is exactly similar to that of a frog without a head?—Yes.

4535. (*Mr. Huxley.*) Have you seen any of the documents which have been published by the Society for the Abolition of Vivisection?—I have; but I cannot say that I have read them with much attention.

4536. You have no judgment as to how far they are fair representations of what takes place within your knowledge of physiology?—I have seen statements made that I consider to be very gross exaggerations, and they really are so hurtful to men who are anxious to do the best they can for suffering humanity that I feel so sore about it that I do not read them.

4537. (*Mr. Erichsen.*) You are, as we all know, a practising surgeon as well as a scientific physiologist. Can you form any idea of what the position of practical surgery would be if many points in connexion with it had not been elucidated by experiments on animals?—I think the best answer that I could give to that for a popular purpose, which I understand is the object of your question, would be to ask any person to read the accounts given by some of the old surgeons, say, the account given in Ambrose Paré's book of the horrors of an operation in his time, and then to turn to an operating theatre as we know it to exist at the present time, and for any impartial person to ask himself how much of that vast improvement is due to experimentation upon animals. Chloroform itself was discovered by distilling a certain acid from red ants, and it is due therefore to experimentation upon animals. If we compare the horrors at the time when red hot knives were used in amputations with the practice at the present time, I do not think any impartial person could shut his eyes to the enormous advantages that have arisen.

4538. Taking the illustration you have just given us, we have had it in evidence abundantly before us that the circulation of the blood was in a great measure determined by experimentation on animals. Ambrose Paré lived in the years towards the middle of the sixteenth century, and the discovery of the circulation of the blood was made at the commencement of the seventeenth. Is it your opinion that these practices that you mention, amputation with red-hot knives, and matters of that description, which went on in Ambrose Paré's time, were in a great measure due to surgeons not being acquainted with the true mechanism of the circulation?—Yes; no doubt they were; but you must remember, as is stated by Cooper, Sprengel, and others, that for 100 years after Ambrose Paré discovered the ligature the cautery was used in the *Hôtel Dieu* in Paris; because Paré was born before Bacon, and it was not at that time the habit to demonstrate experimentally these things as it would be in the present day; but obviously if experimental physiology had been then in vogue as it is now mankind would have been saved for about 100 years the torture of the cautery. Though I quite admit that what you say is most important it would all have come about even sooner if experimentation had been in vogue.

4539. Take such a disease as that of aneurism; could its pathology and method of cure have possibly been known if we had not been previously acquainted with the mechanism of the circulation of the blood?—I think not.

4540. And, therefore, as the discovery of the mechanism of the circulation of the blood is due to experimental physiology, we could not have been acquainted with the proper treatment of such a disease as aneurism, except, indirectly at all events, through the medium of experimental physiology?—That is quite my view.

4541. Have you ever had occasion to make experiments on animals directly bearing upon surgical practice?—Yes.

4542. Would you mention a few instances?—The two most important practical points that I have myself experimented upon have been the torsion of arteries and the transfusion of blood.

4543. With regard to the torsion of arteries, which is now very greatly used as a substitute for the ligature, the knowledge that we possess upon that point was due in the first instance to experiments made by French surgeons and physiologists, I think, at the commencement of this century?—Yes, by Amussat and others.

4544. Will you kindly explain to the Commissioners what the torsion of arteries is?—After Ambrose Paré discovered the ligature it was usual to tie vessels with silken threads, and these threads are left in the wound to come away after some days. Nowadays, many surgeons, myself among others, and some of the leading surgeons in the hospitals of London, catch the end of the vessel and twist it with a pair of forceps in a peculiar way, and the twisting secures the end of the vessel completely, so that you can avoid the leaving behind any threads to irritate the wound; the artery gets sealed up as it were in a peculiar way at the end.

4544*a*. And that process, simple as it appears, is somewhat complex in reality?—Yes, it requires care and is really complex.

4545. And its complexity and the proper method of effecting it has been determined by experiments upon animals?—I have done so myself; Mr. Bryant and Professor Humphry, of Cambridge, made experiments on the same subject. I never could have ventured to do it on a human being until I had made sure that it could be done successfully on an animal first.

4546. In the event of surgeons not being able to experiment on animals they would have to make these experiments on human beings, or else the progress of surgery would be materially arrested?—Everything in the progress of surgery is tentative, and the trial must be made either on a human being or an animal.

4547. And you consider, I presume, that it is wiser and more humane to do it on an animal than on human beings?—Yes, that is my idea of humanity. On transfusion I also made some experiments. Transfusion, I may explain to the Commissioners, consists in replacing the blood of a patient who is dying from hæmorrhage, by the blood of an animal or a human being; it becomes necessary to inject it into the veins of the individual who is dying. I have performed this operation myself a good many times, and on some occasions with very brilliant success. Obviously an object of this kind must be investigated on the lower animals before one has the courage to try it on a human being.

4548. Are there not special dangers connected with transfusion, such as the entrance of air into the veins, and the entrance of clots into the veins, the dangers of which have been demonstrated by experiments on the lower animals?—Yes.

4549. Conditions which, unless they are attended to, would certainly render transfusion a fatal instead of a salutary operation?—Yes, certainly fatal.

4550. That question about the introduction of air into the veins of animals, mixed with blood, is a matter of great importance, is it not?—Yes.

4551. Is it not a source of great danger and of death in certain operations in certain regions of the body?—It is; it has been so.

4552. And the method of death in those cases was not understood until experiments were made, also by the French physiologists I may say, on the lower animals?—I think they threw light on the subject.

4553. It was suspected but not exactly understood?—Yes, and the same for clots.

4554. (*Chairman.*) Could those experiments in

R. McDonnell,
M.D.

2 Nov., 1875.

torsion and transfusion be performed under anæsthetics ?—Yes.

4555. (*Mr. Erichsen.*) The experiments on torsion, I presume, you have always done under anæsthetics ?—Yes.

4556. It is easier to do them so ?—It is positively easier, apart from motives of humanity.

4557. (*Sir J. B. Karslake.*) Is the whole of the experiment carried out under anæsthetics ?—No, because it belongs to those experiments in which the effect must be observed.

4558. How long is it necessary to keep an animal alive for the purpose of ascertaining the effect ?—In such a case as that the animal might be allowed to recover altogether, because the pain is slight. The pain of the operation is severe, but the pain of the subsequent part is so almost nil that it would be humane in fact to allow the animal to recover altogether.

4559. (*Lord Winmarleigh.*) But the severe portion could be done under anæsthetics ?—Yes.

4560. (*Sir J. B. Karslake.*) You would think it a cruel sacrifice of life after having performed that operation to sacrifice the animal ?—I should.

4561. And the animal might enjoy life if allowed to live after it ?—Yes.

4562. (*Mr. Erichsen.*) A dog, for instance, whose femoral artery has been twisted, is perfectly happy in the course of an hour or two afterwards ?—Yes, the suffering is not acute. The animal would not suffer more than if his ear had been bitten in a fight with another dog. We do not kill dogs to save them from such pain as that.

4562*a*. There is no sign of suffering ?—No.

4563. (*Mr. Hutton.*) I understood you to say in answer to Professor Huxley that, as far as your experience went, anæsthetics are always given to all classes of animals when painful experiments are made. Did you include frogs ?—Well, I constantly do use chloroform for them; I put them under the influence of chloroform, and even tadpoles.

4564. And have you found no difficulty in that; because we have had witnesses before our Commission who stated that they never thought it worth while to produce anæsthesia in frogs ?—It is not difficult. I have a simple mode; a little chloroform is diffused through water, and if the tadpole is put swimming about in it for a few minutes, there is enough of absorption through the skin to render it soon insensible, and it can be placed under the microscope for a time and will not stir.

4565. And you would recommend that in all experiments on frogs ?—Yes, I always do recommend it.

4566. I understand that you would disapprove of young men, at least before they had completed their education, being allowed to make any experiment at all ?—I am quite sure if it were attempted in our schools it would be at once put a stop to. We have no rule prohibiting it, but that is because the evil does not exist. I refer to painful experiments.

4567. And you would disapprove of it until the students were at least accomplished physiologists ?—I should disapprove of students experimenting as a rule.

4568. Do you or do you not find any great inconvenience from not having any experiments in the Dublin medical schools under chloroform by way of demonstration ?—I myself should approve of physiological lectures being even more demonstrated than they are at present in Ireland in all those cases where it can be done with the use of anæsthetics, and where it can be done without pain. I think that the demonstration experimentally is so very important to fix a fact on the mind of a student, that where it can be done with a certainty of saving pain, I would be in favour of its being done more frequently than it is at present.

4569. But you would disapprove of painful experiments before classes ?—As a general rule, certainly; I do not say invariably; I think there are some of that kind which it is necessary to show; but, as a rule, I should disapprove of it.

4570. As to those experiments you referred to on sensibility, what would be the longest time for which the animal would suffer before it would be possible to destroy it ?—That is a question very difficult to answer; because sometimes the shock of the experiment will make it necessary to allow an animal, to a certain extent, to recover in order to see the condition in which it is; but I should say never long, it is always a brief period.

4571. Were there not some of those experiments of Dr. Brown-Sêquard's in which the animal was made to rotate for a very long period after the puncture of some particular point ?—The animal is quite insensible during that experiment, it is an epileptic fit; and judging from what we know of human beings in that condition the animal I believe, is perfectly insensible. It is a convulsion accompanied by insensibility. I have repeated that experiment myself, and I am convinced that it is absolutely free from sensation.

4572. (*Mr. Huxley.*) I am not quite sure whether I understood the sense in which you object to students experimenting; whether it is that you object to their conducting experiments by themselves in a room, which is one view of the case; or whether you would also object to their making experiments in a physiological laboratory under the direction of a professor of physiology. Does your objection apply to both of those cases ?—No, but I am in a difficulty in answering questions on the subject because "experiments" cover such enormous ground. I do not suppose anybody would object to a student looking at the circulation in a frog's web, or watching the effect of a grain of mustard seed placed on the frog's web under the microscope. These are very important things to be understood, and we cannot too early accustom our students to observe them.

4573. May I interrupt you so far as to ask you to suppose that an objection has been raised here to the study of the circulation in the frog's web ?—Some of these experiments are absolutely free from pain. You cannot say probably that when a grain of mustard seed is placed on the web the frog is absolutely free from pain; but the pain is really so insignificant that we should have no objection at all to suffer it ourselves. Physiologists have over and over again subjected themselves to far more painful experiments; and the training of young men in a knowledge of the processes of acute inflammation is so important and the good to be obtained so great that I should be in favour of such experiments being done under the wise direction of a professor in whom you would have some confidence.

4574. (*Chairman.*) I understand you now to be speaking of an amount of pain so slight that if it would answer the purpose you would almost submit to it yourself ?—Yes; I have plunged my hand arm for some minutes into a pan full of melting ice and water, as Brown-Séquard has, and that involves torture; and I have given my own blood to be transfused, as Brown-Séquard also has; and I think that is the strongest proof that can be given that we have faith in our cause, that we believe we are doing good by experimentation.

4575. (*Mr. Hutton.*) Would you shrink from an exceedingly painful experiment for the sake of a mere physiological result, an experiment involving agony protracted for many hours for the sake of mere addition to physiological science ?—But we never know how great the result may be. I would not submit to it if I did not think there was some good in it. It is not from idle curiosity that this is done, but the man of science never knows how great the result may be. When Galvani first saw the frog's legs jumping by electricity he never knew that the result would be to bind the whole world together by the electric telegraph.

4576. But the result of that logic is that supposing any number of painful experiments, even of an agonizing kind (and we have had many such named before this Commission which have been tried abroad in a true scientific spirit), the prospect of the pain caused to the animals would not be a sufficient consideration

R. McDonnell, M.D.

2 Nov. 1875.

to induce you to object to them at all?—I do not say that. That is what makes it so difficult to draw the line. One person may estimate the result as very important, and another person may estimate the result as very unimportant.

4577. Supposing anything like a physiological inspection was carried out, that a really great physiologist were appointed to prohibit experiments which he thought useless, of course in that case he might prohibit a great many that would be really useful, without intending to do so; but still would you not think that that would be desirable, considering that he would probably prohibit a very much larger number that would be really useless, and would cause a great deal of animal suffering?—It is precisely in that direction that I see the difficulty; because we are sometimes in ignorance with regard to the use of a discovery; it may be something enormously great, and it may be nothing.

4578. We are not in ignorance in regard to the pain, and supposing the experiments to be extremely painful, then you would be quite sure that you were getting rid of that evil by prohibiting them?—Yes, but you do not know what you may deprive mankind of. Chloroform was discovered by Dumas, the French chemist, by making a certain acid from the red ant. I suppose thousands of these creatures were distilled to get a little formic acid. When he made that discovery he never dreamt for one moment that the great blessing which chloroform has conferred upon mankind would be the result. The man of science never can know the precise benefit which will arise from the discovery of a scientific truth of that kind; he can only be led on by the hope that it will be a benefit some day. And that is what is really the difficulty in my mind, dealing with it in this point of view. I think it would be desirable to lessen the amount of suffering to animals, but that is where I see the very great difficulty of the subject of inspection.

4579. But supposing, as a great physiologist from Ireland has told us, that nine-tenths of these experiments are made by men who are really not competent to discover anything, and that only the remaining one-tenth are made by physiologists with the gift of discovery, would you not think that the enormous amount of pain avoided by prohibiting these nine-tenths would be more than an equivalent for the loss of a certain amount of discovery?—I should entirely differ from that assertion of the Physiologist from Ireland. I should not say for one moment that nine-tenths of the physiologists are people who have no distinct object in view.

4580. No gift of finding their object, no gift of discovery, I said?—Every man has a gift of discovery if he chooses to be a careful observer. The experimental physiologists of Europe and America are a very small number of all the persons who engage in scientific investigations; but, certainly, if you take them all altogether (and I have known personally a great many of the most distinguished of them), none of them can be said to be deficient in the gift of discovery; there is in fact no such thing as a gift of discovery, it is a patient, painstaking carefulness, and a desire to record certain facts truthfully; and a very humble man with limited intelligence may possess that. In fact I think it was Galvani's wife who saw the frog jump upon the plate, and made the discovery which has done everything for us in electricity. She was a delicate lady and was ordered frogs; they were upon a plate in the laboratory, and she drew her husband's attention to the fact that a spark from the machine made them jump.

4581. (*Mr. Huxley.*) You would be quite familiar with the publications in Pflüger's Archives, with those in Brown-Séquard's Journal, and in fact with the periodical publications on physiology and physiological subjects?—Yes.

4582. Now taking the papers which appear in those publications, would it not be an entirely misleading statement to say that not one-tenth of those are of any value?—I should certainly differ entirely from any such assertion.

4583. If one put it the other way and said that it is not one-tenth that would turn out to be of no value, that would be nearer the fact?—I should think that would be nearer the truth.

4584. (*Chairman.*) You do not like to give general answers upon the relative importance of experiments as compared with the pain which they inflict; you would prefer, I suppose, to know the precise case before you gave a positive opinion?—I should.

4585. But I do not understand you at all to differ from what you said in a former part of your evidence, namely, that of the experiments which you think ought to be made upon living animals, by far the majority may be made under complete anæsthesia?—Yes, clearly.

4586. That of the remainder, where complete anæsthesia cannot be obtained, many experiments are of a nature in which the greater part of the pain may be removed by anæsthetics, and the remaining part will be very small?—Yes.

4587. That what remains after those two portions have been deducted is chiefly the class of experiments upon sensation; that those are very rare, that where the result has been sufficiently verified before, you object to repetition; and that in the few cases which still remain you do not contemplate protracted agony. Have I rightly represented your views?—Exactly.

4588. That as regards the protection of the physiologist from undue suspicion on the part of the public, you think legislation would be desirable?—I do. I think legislation would be desirable, although I see great difficulties in the way of carrying it practically into effect.

4589. And that unless it could be carried into effect in such a manner as to prevent its interfering with the progress of scientific discovery in the hands of the most competent persons, you would hesitate to give it your approval?—Yes.

4590. But that if a mode of carrying it into effect were devised which should be free from that objection, you would then think it a benefit to the highest persons in science?—I should.

Mr. T. Hayden.

Mr. Thomas Hayden called in and examined.

4591. (*Chairman.*) I think you are professor of anatomy and physiology in the Catholic University of Ireland?—Yes.

4592. Are you a practising physician?—Yes.

4593. And a fellow of the College of Physicians?—Yes.

4594. Have you paid attention to the subject which is referred to us?—I have.

4595. Would you be so good as to state your views upon it to us?—I have been for some 20 years teaching anatomy and physiology. In the early part of my tenure of office as professor I thought it my duty to perform experiments upon animals, with a view to satisfying myself in regard to certain cardinal points connected with the science of physiology. I performed the experiments alluded to upon dogs, rabbits, the lobster, et cetera.

4596. Were these experiments performed under anæsthetics?—All those upon dogs and rabbits were performed under the influence of chloroform.

4597. And with regard to the lower animals?—No anæsthetic was used in the case of those animals. I doubt whether in their case anæsthetics are of any value. The experiments which I performed had reference to the rhythm, or cyclical movements of the heart, the peristaltic action of the intestines, and the rate of transmission of the contents through the intestinal canal. They had reference also to the effect upon the elaborated chyle, the product of digestion, produced by various substances containing fats and sugars, and substances not containing fats and sugars. These experiments were, most of them, performed in the presence of my class; but having satisfied myself upon the points that I wished to be satisfied upon, I ceased to perform these experiments, and for many years past I have not performed any upon living animals.

4598. Then I need scarcely ask you whether, for the instruction of students, you consider it necessary to perform experiments upon living animals?—My conviction is that it is not necessary; and furthermore, I may take the liberty of remarking that I do not think the majority of students profit much by it.

4599. You think that the profit to be derived from it arises at a later period of their professional career?—Yes, or when they are senior students.

4600. Now, you have said that your own experiments, so far as they relate to the higher class of animals, were all performed under chloroform or other anæsthetics?—Yes.

4601. Is it your opinion that now that chloroform has been discovered, it is necessary for educational purposes to subject animals to any experiments at all in which they are conscious of pain?—I do think it is necessary, but within limits. I think those experiments should have reference to subjects in which there is still something to be discovered. I may exemplify that by referring to the experiments which are now being performed with such benefit to science by Professor Ferrier in London, and by Professor Rutherford in Edinburgh, by the latter in regard to the secretion of bile, and by the former in regard to the convolutions of the brain. That is quite new ground, and I conceive it quite impossible without detriment to science to dispense with experiments in these departments.

4602. By that you do not mean to say of Professor Ferrier's experiments that those which appear to an unlearned person who reads the description to be very painful, are really performed while the animal is in a state of consciousness, do you?—I do not know that he has been in the habit of using anæsthetics in all his experiments; I am not quite aware as to that; I am not informed as to details; but it is well known that experiments performed on the surface of the brain are not attended with very great pain.

4603. Then may I say generally that your own opinion is that for the instruction of young students experiments giving pain to animals are unnecessary?—I would say so. There may be exceptions, but they are not at present before my mind.

4604. We have understood that in Ireland, among the educated portion of the Irish people, there is a very strong feeling on this subject; is that your view?—Yes, I am aware that there is a strong feeling.

4605. That the notion of subjecting animals to great and protracted suffering would be abhorrent to them?—Yes.

4606. Are there any other observations which you wish to make to us?—None that occur to me now.

The witness withdrew.

Dr. John Cleland, M.D., called in and examined.

4607. (*Chairman.*) Are you professor of anatomy and physiology at Galway?—Yes.

4608. Have you paid attention to the subject which has been referred to this Commission?—I have paid attention to it.

4609. Would you state to us the extent to which you have been acquainted with the practice of experimenting upon live animals?—I do not profess to be a vivisector myself; that is to say, I practice it to a very small extent; to some extent, but not to any considerable extent. I am familiar with the work that it has done for physiology, and I am familiar with the practice in the hands of others. For example, I have seen vivisection carried out in Leipsic, where there is the greatest facility for experiment probably that there is in any school.

4610. Have you been accustomed in your teaching to exhibit experiments upon living animals?—I have never exhibited experiments on any animal higher than a frog, I am sorry to say, but the reason is that I have not the facilities. You will observe that I am professor of anatomy as well as of physiology. The subjects are so very great that they are in reality more than any one man can fully overtake. The consequence is that I have to select my methods as well as my matter, and that is the reason why, as I have mentioned to your Lordship, I have not carried out vivisection myself.

4611. You have formed, I daresay, an opinion whether, when experiments are performed upon living animals, for the purpose of demonstration to students, they ought or ought not to be limited to such experiments as can be performed under anæsthetics?—I am not prepared to say that they should be limited in any way. I think that that must be left entirely to the teacher's discretion. Undoubtedly anæsthetics ought to be given in every vivisection where it is possible; that is to say, where it does not interfere with the object of the experiment; but I would be most unwilling to lay down any hard rule on the subject.

4612. Would the number that can be performed under complete anæsthesia be the greater number of experiments?—Yes, probably.

4613. Whether for original research or for demonstration to students?—I should say that the majority can be performed under an anæsthetic; that is to say confining ourselves to experiments on mammals.

4614. Have you ever considered how far frogs can be anæsthetised?—I have tried to make up my mind how far the frog feels at all; and I own that I have not come to any conclusion on the subject.

4615. We had a witness a little while ago who told us that he can anæsthetise frogs and tadpoles; you being in doubt whether they are sentient or not, would you prefer to employ such a method?—I frankly own that it never occurred to me to apply anæsthesia to a frog. One would not think of applying anæsthesia to a worm before using it for a bait in fishing.

4616. Then you admit that you are in doubt whether frogs feel or not?—I have very little doubt indeed that they do not feel pain in a sense comparable with that in which we are familiar with it ourselves, because it seems impossible that they can have consciousness at all comparable with ours; the degree of consciousness that they have I cannot say. I believe that consciousness goes down a great deal lower than the frog. But these are matters of speculation. What I feel sure of is that a frog's consciousness is such a twilight thing compared with our consciousness, that it is a difficult matter to estimate its degree.

4617. But you are of opinion that in mammals at least anæsthetics should be employed?—Whenever they can be.

4618. Have you ever considered whether any limitation ought to be imposed upon the power of teachers to perform painful experiments?—I have considered that, but have come to the conclusion that there ought not to be any.

4619. You think that every teacher should be at liberty to perform any experiments, painful or otherwise?—I referred to those whom one knows in schools usually as qualified teachers. By that I mean men who, from various considerations, may be supposed to be familiar with the subject that they are teaching.

4620. But if they were not so qualified, then you think they ought to be restrained?—It does not seem to me that further restraint is required than that which is provided for already by the Cruelty to Animals Act. The same punishment that would come into operation in the case of a boy being cruel to a cat for play would, I fancy, reach everything that requires to be reached. I cannot say that, after thinking over it very much, I see any reason for legislation on the subject.

4621. Are you aware that the Cruelty Acts only apply to domestic animals?—No, I did not know that. However, I suppose, a rabbit might be considered a domestic animal, and a dog certainly is.

4622. Then you think that at any rate some protection ought to be given to rabbits?—I think that there is no further need of protection for rabbits, the tame rabbits that are always used for these purposes, than what would be afforded by their being considered as domestic animals, and therefore as coming under the general Act.

4623. Would the same observation apply to guinea pigs?—I presume so; they are tamed animals.

4624. And to rats?—To tame an animal and keep it and feed it is, to a certain extent, to domesticate it. I think there would be no great stretch, therefore, in applying it to rats so tamed.

4625. But supposing that rats are not domestic animals, do you think that if it were proposed to leave anybody free to perform experiments upon rats, there would be any necessity for any change in the law?—I see no objection to including all mammals under the present Act; to widen the present Act to that extent.

4626. (*Lord Winmarleigh.*) What makes you believe that the frog is less sensitive to pain than one of the higher animals?—There are the anatomical considerations to begin with, the conformation of its brain and its spinal cord, the nervous centres. With regard to the conformation of the brain it has a very low organization in fact.

4627. You have convinced yourself of that by your own examination, not by what you have heard, I presume?—I am familiar with the anatomy of a frog's brain.

4628. That is from your own examination?—Yes.

4629. It is not from anything that you have read or collected of the opinions of others?—I cannot at the present moment say that I have actually made a careful dissection of a frog's brain; but I have of so many animals both higher and lower, and the anatomy of a frog's brain is so thoroughly well known, that I cannot imagine that the gap in my own personal dissections can make any difference. I have no rational doubt of the anatomy of a frog's brain.

4630. What is the exact circumstance which has chiefly led you to believe that the frog is less sensitive to pain than other animals?—The cerebral hemispheres in the frog are very slightly developed; and as you pass to animals that have less and less complex brains, you have got less and less sign of intelligence; and further, we know by experiments which have been made on both birds and mammals, that if you remove that part of the brain called the cerebral hemispheres in portions, the more that is removed the fewer signs of consciousness are left; and I do not think that there is any reason to believe, from the experiments that have been made on the subject by Flourens and others, that a bird that has had its cerebral hemispheres removed has anything that can be said to be comparable with our consciousness.

4631. I understand then that you have derived this opinion from the writings of others?—It is one of the things that we have from vivisections.

4632. The object of my inquiry was to ascertain whether your own experiments had led you to coincide with that opinion?—I have not made vivisections myself on the subject; I should not wish to put the results of any vivisections of my own before the Commission. With regard to frogs I may observe that, on the assumption that they feel pain in the same way that we do, we have a right to suppose that the seat of their feeling is in the brain; and in the great majority of experiments that are made on frogs we are in the habit of commencing by either pithing the animal or decapitating it. It may be my fault, but I never thought of including this practice under the head of giving an anæsthetic to a frog; I should certainly at once decapitate it or pith it, when that could be done.

4633. (*Sir J. B. Karslake.*) How long have you been engaged in lecturing to pupils?—One way or other I have been engaged in lecturing since 1857. I began as demonstrator of anatomy in 1857; I have held my present chair for 12 years.

4634. That is to say you commenced as professor of physiology 12 years ago?—Yes; at Christmas 1863.

4635. Do I understand you rightly to say that you have never or only rarely practised experiments on living animals before the class?—Only rarely.

4636. Did you say that you regretted that you were not able to do it to a greater extent?—I do say so.

4637. In your judgment is it essential for the satisfactory education of the class that they should see a further number of experiments upon the living animal?—I think that it would be more satisfactory. I think that I should do my duty still better to them than I do if I had the opportunity to illustrate much more fully than I do by means of actual experiments.

4638. Do you think that reading alone will supply that want?—I do not think that reading in anything will supply the want of actual observation on the part of students; thus, in anatomy, the other subject which I have to teach, no amount of reading can take the place of dissection of the human body. I give that as an example of the general proposition which I lay down, that direct observation is desirable where it is possible.

4639. And you think that it is as necessary to carry that on by experiments on living animals, if you can possibly do so?—The object of my teaching physiology is to educate medical students. I have got a great deal to teach in the six months course, and I must select my matter. I think that I should be doing wrong if I missed out a great deal of the matter that I now give them, to occupy them with experiments that require a great deal of time; but for any student who has got a knowledge of physiology otherwise, to have added to his information the observation of experiments on animals, I consider a very great advantage.

4640. (*Mr. Huxley.*) I presume, from what you have just said, that the curriculum of medical education is, in your judgment, very heavily weighted at present?—It is.

4641. And, therefore, whatever might be your desire as to the thorough teaching of physiology, I understand you to say that you would hardly feel yourself justified in occupying so much of the students time upon that subject as you would need to do if you taught it practically, having regard to the other things that they have to learn?—Quite so.

4642. But that does not in any way diminish in your judgment what I may call the abstract importance of demonstrative teaching?—It does not; besides, I frankly own that such teaching as mine does not produce physiologists. I produce medical men, but I do not produce physiologists.

4643. I would now ask you a question which might perhaps surprise you, but you will understand that I have a motive for asking it. If the alternative were put to you in experimenting upon one of the higher animals, in a case in which it was possible to use anæsthetics, whether you would use them, or whether you would not, would you have any hesitation as to what you would do?—If the experiment would not suffer by it, in the case of a mammal, I should use the anæsthetic.

4644. That would be a matter of course, would it?—Yes, certainly. The first experiments of the sort which I made many years ago (I was only operating along with another), were made on cats; and although there were very few of them (I cannot now tax my memory as to the number, for it was many years ago), and although it was a matter of sensation

Dr. J. Cleland, M.D.

2 Nov. 1875.

that we had to deal with, we gave chloroform to the cats before the performance of the operation, and then when the effect of the chloroform went off, tested the presence or loss of sensation in the parts supplied by the nerves that had been divided.

4645. You have not only been for some years professor of physiology, but you were for a long time I think one of the demonstrators in the Great Anatomical School of Edinburgh, were you not?—Yes.

4646. And you must have had an opportunity of seeing a great deal of what is done there?—Yes.

4647. Now did it ever come to your knowledge that a person pursuing an experimental inquiry would, in such an alternative as I have just placed before you, hesitate for a moment as to what he would do?—I do not believe he would.

4648. At any rate he would not justify it if he did? —He would not. It is perfectly possible that he might have something to do which he thought would give so little pain, that he might deal with it in the same way as we surgeons deal with cases every day of our lives, as I have often dealt myself in operating on living human beings, namely, take into consideration whether the amount of pain that was to be given was worse to bear than the giving of the anæsthetic. I am quite sure that anything that could be by any twisting of the word called torturing an animal would not be done without giving an anæsthetic. That is my own opinion.

4649. Have you seen any of the proposals that have been brought forward for the regulation of vivisection for scientific purposes?—I have not.

4650. (*Mr. Hutton.*) As to demonstrative experiments generally, has your attention been called to this Handbook of Physiology edited by Dr. Burdon-Sanderson, that has been recently published?—Yes, I am familiar with it.

4651. It contains a great number of painful experiments. Would you regard the larger number of those experiments as fit to show a class by way of demonstration?—If I were lecturing myself, and exercising my own judgment, it would be a very select class indeed to which I should show a very great number of those experiments; and that for the reason which I have already mentioned, that the great majority of students have their time taken up so much with other things. But if I were bent upon sending out thorough physiologists, I think I could have little doubt in considering that handbook as a very useful one to go by.

4652. And that even for purposes of demonstration and teaching; not for purposes, of inquiry, but for those of demonstration?—Yes; that they might see, and not take things on hearsay.

4653. Did I not understand you to say that you had studied under Ludwig, at Leipsic?—I said that I had seen their method of pursuing studies there. I have not myself studied under Ludwig.

4654. There, I suppose, a very much larger number of painful experiments are used in demonstration than are generally used in England and Scotland?—The majority of the experiments that are performed in the Leipsic establishment are for purposes of inquiry, for purposes of research, but they do also illustrate before a class.

4655. And you are in favour of extending the system, at least for classes of physiologists as distinguished from medical men, I understand, of a much larger demonstration of painful experiments?—I am in favour of every professor of physiology having nothing but physiology to teach; and where he has nothing else to teach I am sure that he would be better able to demonstrate it by vivisection than I am able to do; but from various motives the chairs of anatomy and physiology are combined in the Queen's Colleges.

4656. That you consider a great evil, as I understand?—I think it is too much for any one man to teach.

4657. But if you had a separate class, for separately educating physiologists as distinguished from medical students, you would not scruple to use a great number of painful experiments by way of demonstration?—I should certainly consider it my duty to perform certain experiments.

4658. (*Chairman.*) Did I rightly understand you to say, with regard to the frog, that though you did not administer anæsthetics, you either what is called pithed the frog, or removed the brain, or took away the sensibility of the frog in some manner of that sort? —Yes. I did not understand the question about anæsthetics to reach to that; I do not say but what the word may be used as applying to these procedures, but it did not occur to me at the time. I thought of giving chloroform, and so on.

4659. It did occur to you, however, as I understand, to remove whatever sensibility there may be in the frog by removing the brain?—Yes.

4660. You have just been asked whether you would, if you were a teacher of physiology only, perform a considerable number of experiments of a painful nature; but I want to know whether the consciousness of the mammal would not be removed by chloroform, or some other anæsthetic, before the experiment was performed?—Certainly, wherever that could be done; but I think there are painful experiments that may be performed even on mammals. I am not prepared to limit even the performing of painful experiments; I would not lay down a rule; I think it is for each physiologist to judge for himself. I think that the more educated physiologists are the better they will be able to perform experiments in such a way as to get the knowledge with as little pain to the animal as possible. It is always an object to damage the animal as little as possible in an experiment, and I think it is quite possible that in the present, I may call it transition stage of physiology in this country, there is many an animal treated with less skill than it would be if physiology were as well studied as it is in a number of Continental schools.

The witness withdrew.

Adjourned to to-morrow at 2 o'clock.

Wednesday, 3rd November 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

Mr. CHARLES DARWIN called in and examined.

Mr. C. Darwin.

3 Nov. 1875.

4661. (*Chairman.*) We are very sensible of your kindness in coming at some sacrifice to yourself to express your opinions to the Commission. We attribute it to the great interest which we know you take in the subject referred to us, both on the score of science and also on the score of humanity?—Yes, I have felt a great interest in it.

4662. I think you took part in preparing the reso-

Mr. C. Darwin.

3 Nov. 1875.

lutions of the British Association at their meeting in Edinburgh in 1871?—No; I had nothing to do with that. I was very glad to see them, and approved of them; but I had nothing to do with the framing of those resolutions; I did not attend the meeting.

4663. But you signed a petition which embodied them?—When they were sent to me I may have done so. I do not remember it; but if my signature is attached I must have given it; I had forgotten it.

4664. But you cordially approved of them?—I cordially approved of them. I had occasion to read them over lately at the time when this subject was beginning to be agitated. I read them over with care and highly approved of them then.

4665. I think you took some part in the preparation of a Bill which was ultimately laid before the House of Commons by Dr. Lyon Playfair?—In the steps preparatory to that Bill, but the Bill itself did not exactly express the conclusions at which after consultation with several physiologists we arrived; I apprehend that it was accidentally altered.

4666. But in the main you were an approving party?—In the main.

4667. You have never, I think, yourself, either directly or indirectly been connected with the practice of trying experiments upon living animals?—Never.

4668. Will you have the kindness to state to us the views which you desire to lay before the Commission in connexion with it?—The first thing that I would say is, that I am fully convinced that physiology can progress only by the aid of experiments on living animals. I cannot think of any one step which has been made in physiology without that aid. No doubt many surmises with regard to the circulation of the blood could be formed from the position of the valves in the veins, and so forth, but certainty such as is required for the progress of any science can be arrived at in the case of physiology only by means of experiments on living animals.

4669. Then I need hardly ask you what your opinion is as to the notion of prohibiting them altogether?—In my opinion it would be a very great evil, because many reasons, mostly general, but some special, may be assigned for a full conviction that hereafter physiology cannot fail to confer the highest benefits on mankind. Many grounds, I think, can be assigned for this conviction.

4670. Is it your opinion that most of the experiments can be performed while the animal is entirely insensible to pain?—That is my belief; but I ought to state that I have no claim to rank as a physiologist. I have, during many years, read largely on the subject, both general treatises and special papers, and in that respect I have gained some general knowledge, but as I have said, I have no claim to be called a physiologist, and I have had nothing to do in teaching physiology; but from all I can learn, the exceptions are extremely few in which an animal could not be experimented on in a state of entire insensibility.

4671. Then to hesitate to perform experiments, though painful in their nature, when the animal was rendered insensible, would not be, in your opinion, a judicious course to recommend to the Queen and Parliament?—Certainly not. It is unintelligible to me how anybody could object to such experiments. I can understand a Hindoo, who would object to an animal being slaughtered for food, disapproving of such experiments, but it is absolutely unintelligible to me on what ground the objection is made in this country.

4672. Now with regard to trying a painful experiment without anæsthetics, when the same experiment could be made with anæsthetics, or, in short, inflicting any pain that was not absolutely necessary upon any animal, what would be your view on that subject?—It deserves detestation and abhorrence.

The witness withdrew.

Mr. F. Sibson, M.D.

Mr. Francis Sibson, M.D., called in and examined.

4673. (*Chairman.*) Are you consulting physician to St. Mary's Hospital?—Yes.

4674. And a member of the Senate of the University of London?—Yes.

4675. And a Fellow of the Royal Society?—Yes.

4676. Now you have paid a great deal of attention, I think, to the subject which has been referred to us?—I have paid a certain amount of attention to it. Many years ago I did myself perform a few experiments, and within the last 12 years I have performed one short series.

4677. What is your opinion as to the necessity of such experiments?—I would say, as a physician and physiologist, that it does not admit of opinion, but that it is a certainty that experiments are absolutely necessary for the progress of medicine, including all its branches.

4678. The introduction of anæsthetics, I presume, has made a very great difference in the degree of pain to which animals are subjected?—A very great difference. The greater number of experiments that would be performed for the purposes of inquiring into the nature of disease, and the treatment of disease, would be performed under the action of anæsthetics; and I would say the same of those experiments, a great number at all events of those experiments, that are performed in pursuit of pure physiology; but of course in certain circumstances to use an anæsthetic would defeat the object of the experiment.

4679. Are those occasions rare?—Well, you see, I have never been a systematic physiologist, and therefore I should be speaking out of my province if I were to say whether they are rare or common. I should not feel myself competent to give an answer to that question. Most certainly in those points that come into my own cognizance every experiment which we as physicians can desire to perform to throw light upon disease, and the treatment of disease, can either be done under the influence of anæsthetics, or, so to speak, the experiment would be so trivial in its nature as not to require any agency so serious.

4680. That is to say, that the inoculation of an animal for the purpose of communicating to it a disease may no more deserve the use of chloroform than the vaccination of a child?—Certainly.

4681. But in that case the pain and inconvenience is consequent inconvenience, that is to say, being affected with the malady?—Yes, being affected with the malady.

4682. Now when animals are so affected for this purpose, is it necessary to keep them in distress for a long period of time?—It would depend entirely upon the nature of the inquiry, and the object. Of course if it is to inquire into a disease, let us take the instance of the cattle plague; the disease must run its course. If it is to inquire into diphtheria, erysipelas, small-pox, cow-pox, and the various diseases of that class, that have been inquired into, clearly each of them must run its course. But I need not tell your Lordship that the process of a disease is not one of constant pain, but very much the reverse in most instances; and as a physician I can say that in walking round the wards of a hospital, I very rarely see now, or did see when I was in the daily habit of going there, any trace of suffering on the face of any patient, particularly of a fever patient; because, so to speak, there is an anæsthetic within them in the very poison that saturates their blood and solid tissues and nerves; therefore they are lying there scarcely more than just conscious. Therefore I would say that that which applies to mankind applies also to animals; and that they are anæsthetised by the very malady that is produced, as a rule; I do not say in every instance.

Mr. F. Sibson, M.D.

3 Nov. 1875.

4683. Then your opinion is, that in experiments for the purpose of observing disease, the original operation is so slight that in a human being it would be disregarded ?—Quite so; it is scarcely felt.

4684. I understand you that the subsequent distress is in most instances not in your judgment excessive ?—No, I do not think it is, for the reasons I have given; I do not say in every case; as, for instance, in erysipelas; but the suffering from erysipelas is not great. I am taking now those involving the greatest amount of pain. If you come to a boil or a carbuncle, we do not give that in experiments. Scarlet fever gives no pain; certainly if it attacks the throat it does, but that disease is not produced in experiments.

4685. I need not ask you whether, in your judgment, whenever an animal is used for the purpose to which you have referred, the most humane possible treatment should be adopted ?—The most humane treatment should be adopted.

4686. Or whether the persons who are qualified to adopt the most humane treatment are not those who are most skilled in the calling ?—Precisely so. With regard to the question of the spirit that animates the operator, perhaps you would allow me to read a few words that have been put into my hands by one of the most distinguished experimental physiologists with regard to that very point.

4687. May we take them as representing your own views ?—Yes. "The 'rule of kindness' guides us" (that is the physiologists) "just as it guides other " good and reasonable men in dealing with animals. " In making the experiments, we" (the physiologists) " choose our method so as to give as little pain as we " can, and we spend no end of pains in planning and " preparing for them, so that we may obtain out of " each trial the utmost information that it is capable " of giving, and hence to avoid the need of repetition."

4688. Now has the question ever occupied your mind whether any measures might be adopted for limiting such experiments to the most highly qualified persons ?—I have thought the question over; I think that if you were to put anything like a strict limitation on this matter you would, so to speak, clip the wings of the advance of the science of medicine in its highest sense.

4689. But do you suppose that the science of medicine is advanced by inquiries conducted by incompetent and uninstructed people ?—No, certainly not.

4690. If then any restriction that were proposed kept clear of interfering with any but that latter class, it would not be open in your mind to any objection, I suppose ?—I am not fond myself of restrictions; I think that in this country we get on far better by being governed by our own conscience, our own sense of what is right, and public opinion. I think those are far better rules than any minute rules that may be laid down, such as would interfere perhaps with some of the happiest lines of research that have ever been undertaken; and perhaps put a stop to some of the most important investigations and prevent their being undertaken; and do nothing whatever to promote either humanity or the welfare of man by the advance of the healing art.

4691. But that is a rather large answer, and would include a great deal. We are very happy to live in a country which consists of very honest people, and to have a very sound public opinion; but we not only maintain our old laws, but we add a large volume every session to the laws by which we are governed; and I do not understand you to desire that we should entirely repeal all those Acts of Parliament ?—I do not quite see, if you will allow me to say so, how that applies to what I have been saying.

4692. I only applied it to what I considered the comprehensiveness of your answer in which I think you said that we get on best in this country by trusting to public opinion and to our own consciences. Now we have an Act of Parliament which prevents cruelty to animals in certain circumstances; would you object to that Act ?—No, certainly not.

4693. Then supposing that it were proved that there were abuses in regard to experiments upon living creatures, would you object to a law for the correction of those abuses ?—If there were abuses I should certainly not object to a law for the correction of real abuses.

4694. But you think there is no evidence that such abuses do exist ?—I am not at all of opinion that such abuses do exist to a sufficient extent for them to be called abuses requiring legal interference.

4695. But if there were such abuses, then you would think it reasonable to have legislation to restrict them ?—Yes, in a reasonable manner.

4696. (*Mr. Huxley.*) I think that you have been, at some part of your life, if you are not now engaged in teaching ?—Yes, I have taught for some 20 years.

4697. In what branches of medical science did you teach ?—The practice of medicine and clinical medicine.

4698. You have naturally paid great attention to the progress of medical education ?—Very great indeed; it has been part of my daily interest.

4699. I suppose I shall not be wrong in assuming that you consider the increase of practical teaching in the medical schools, in all branches of medical science, as one of the great advances that have been made of late years ?—That is the great advance.

4700. One of the great changes that have taken place ?—Yes, that is the vital change and the vital improvement.

4701. Not only do the examining bodies now insist upon practical study in medicine and surgery, but they also insist upon it in chemistry, do they not ?—Yes.

4702. And arrangements have been made now in all well organised medical schools in which such practical instruction can be given ?—It is so everywhere.

4703. And in accordance with this general advance in the improvement of medical teaching, practical teaching has been introduced into physiology, has it not ?—It has; within the last three or four years physiology has been taught in the schools in a totally different manner from what it was formerly.

4704. May I ask whether you consider that an improvement upon the old style of teaching or not ?—Yes; indeed I think that the old style was scarcely teaching at all; this is really teaching.

4705. And you attach very great weight, I apprehend from that answer, to giving to students such demonstrations as are requisite to put before their minds clearly the fundamental truths of physiology ?—I should put the work in a physiological laboratory and the work in a physiological lecture room precisely in the same position with the work in the medical lecture room, and the work in the wards. It would be as impossible to teach physiology in a lecture room as it would be to teach the practice of medicine in a lecture room.

4706. I presume that, as a scientific practitioner of medicine, you regard an accurate knowledge of the structure and functions of the healthy organism as the foundation of all your knowledge on the subject ?—It is the only certain foundation of a knowledge of disease and its treatment; and in every section of physiology, every single part of the body, the knowledge, and the experimental knowledge of that part leads up to the practical knowledge of the diseases of that part, and of the treatment of those diseases.

4707. Supposing that you, as a physician, wished to understand an abnormal action of some organ, to understand it thoroughly and scientifically, I mean, I presume you would hardly be content with a mere reading knowledge of the normal functions of the organ, but you would go to the thing at first hand, and make out for yourself what the exact basis of those statements was ?—It would be quite necessary to do so; I should not have the least idea of the life within unless I had studied it as an actual living thing elsewhere.

Mr. F. Sibson, M.D.

3 Nov. 1875.

4708. And the confidence with which you would reason from healthy processes to abnormal processes where you had such first-hand knowledge would be very different indeed from that which you would reason if you only had second-hand reading knowledge?—In the one instance I should have knowledge, and in the other it would be a matter of guess work.

4709. I think you have yourself made elaborate investigations upon the normal working of the organs of respiration, have you not?—Yes, I have, a great many years ago.

4710. May I ask whether the knowledge acquired in that way has been of service to you in your professional career?—It has been of the greatest service to me in the study of disease. I began that inquiry in order to study with greater advantage the diseases of the chest, and I pursued it with that in view; and to this hour, I may say every day of my life, the work that I did then I find to be of clinical profit to me.

4711. Then if any legislative measure were adopted which would seriously impede the demonstative teaching of physiology, I gather, from what you have stated, that you would consider it an evil?—It would be turning back the student into the old paths which we now feel to be no longer tenable. The old teaching was not teaching—we all feel that now. In our younger days, unless we did the thing for ourselves, as you very well know, we did not get a true teaching of any single structure in the body; we saw a series of dissections and pictures, but there was no true idea in our minds either of the actual structure or of the living organs which were contained in the body.

4712. I suppose your recollection will carry you back to the time, or at any rate you must know of the time, when even the knowledge of anatomy required by the examining bodies was of an astonishingly minute character?—Yes, it was very slight indeed in my early days.

4713. So that the change which has come over physiological teaching is simply a part of the great change which has swept over medical teaching in general?—It is a part of it, and it came in late. All the rest had got into a practical state when physiology was still merely being taught orally.

4714. It is the fact, is it not, that a great majority of the experiments which are required for demonstration of the fundamental facts of physiology can be quite well carried on under anæsthetics?—I believe so, or under parallel influences, or else they are experiments not requiring them.

4715. You have had the personal acquaintance and friendship of a great many physiological experimenters, have you not?—I have intimately.

4716. May I ask you, from your own knowledge of these persons and from your own work, whether it is not the fact that while they might possibly be inclined to pursue any line of experimentation which would be likely to yield valuable results, whether it involved pain or not, yet all the persons you have known would regard it as a matter of morality, I was about to say, to inflict no useless pain?—I am quite sure that all of them, without exception, are guided by humanity and kindness towards the animal they are experimenting upon as the leading principle, and their desire is to inflict the least pain that they can.

4717. Even if a man had, by carelessness or misadventure, made an experiment which was painful when it was possible that the animal might have been made insensible, if the fact were brought to his mind he would be ready to admit that it was a wrong thing?—Certainly.

4718. (*Mr. Erichsen.*) Have you ever found any English physiologist advocate the doctrine that the animal should only be anæsthetised for the physiologist's convenience irrespective of the relief of suffering to the animal itself?—No, I have never heard it.

4719. Such a doctrine is utterly unknown, so far as you know, in the schools and amongst the physiologists of this country?—Quite unknown.

4720. (*Chairman.*) And such a doctrine, if it obtained any footing in this country, would merit repression by legislative interference, I presume?—I cannot conceive it possible that such a spirit should come into this country. If it did come it must be repressed.

4721. (*Mr. Erichsen.*) Having been a teacher in one of the large schools of medicine in London for a very considerable number of years, do you believe that the students of that school, taking them as a sample of the medical students in London generally, would tolerate practices founded upon such a doctrine being carried out before them?—I am quite sure that they would not, judging from the spirit of humanity, and I would say a remarkable fondness among all the young men that I was acquainted with for the domestic creatures that they come in contact with.

4722. Many of the medical students, a very large number of them, come from the country, do they not?—Yes.

4723. And in the country they are addicted during their vacations to field sports and ordinary amusements as much as any other young men?—Yes.

4744. And they would be as likely as any other set of young men in your opinion to repudiate any unnecessary cruelty inflicted upon animals, such as dogs, horses, &c. with which they came in contact in other ways during the period of their vacations, and perhaps antecedent to the period of their studies in London?—Yes.

4725. So that I presume I may conclude that you would not think that an experiment would become attractive to medical students in proportion to its frightfulness?—I am sure that it would not; that it would be impossible to present a frightful experiment to them.

4726. That instead of being more attractive it would become less attractive?—It would be stopped by them I am quite sure.

4727. Many of the experiments that you made, I think, if I recollect right, had a direct bearing upon practical medicine?—Yes, I think they all had. One set was upon the action of opium; and I took part in another set as a member of the Chloroform Committee of the Medical and Chirurgical Society; another set was on the movements of the heart and the action of its cavities and valves, which were in direct and immediate relation to the diseases with which the heart is affected.

4728. And may I ask you whether it is the case that these experiments which you have made upon the action of the heart and its valves have or have not been quoted in works on disease of the heart as illustrative of various questions connected with the diseased action of the heart?—Yes, they have. A work just come out has given some of my experiments; in fact drawings which I published have been copied into the work.

4729. In speaking of the pathological aspect of experimentation on animals you stated that the majority of the diseases which were induced pathologically were not painful?—Yes.

4730. There is one disease that you have not mentioned, but which has been spoken of here as an extremely painful disease induced in animals, not that its induction is painful, but that the disease in its progress is attended with great suffering to the animal; I mean tuberculosis. Now is it your opinion that tuberculosis of the internal organs is a painful disease?—I know it not to be a painful disease, but a disease quite free from pain. I do not mean to say that in some occasional manifestations of inflammation there may not be pain; but it is remarkably free from pain, and you know tuberculous consumptive people are of all people most buoyant and full of life, and free from every idea of death, and so full of animal enjoyment that you cannot restrain them.

4731. Knowing that to be the case when the internal organs of men are saturated with tubercle, is there any reason to believe that when an animal has

Mr. F. Sibson
M.D.

3 Nov. 1875.

had tubercle communicated to it artificially it should suffer more than a human being who has either inherited that tubercle, or in whom, as it is now the opinion of some, that tubercle may have been implanted by actual contagion?—It is quite certain, indeed, it is a matter of scientific knowledge, that there is no difference between the tuberculosis so induced and that which is inherited or acquired by the habits of everyday life.

4732. So that I may take it as your opinion, as a physician of large experience, having seen much of tuberculosis, that tuberculosis of the internal organs in any way induced is not a painful disease?—Not a painful disease, but the very reverse.

4733. (*Mr. Hutton.*) I suppose you would think that the experimental method has increased very much in England since the time of Sir Charles Bell, would you not, as well as abroad?—I should say that it has certainly.

4734. If a method in general increases, I suppose you would expect its abuses to increase in the same proportion; if the number of experiments in all increased, the number of useless experiments would probably increase too, would it not?—That is one of those questions (you will pardon me, I hope, for saying so) that I think almost answer themselves. Confining myself to the subject in hand, I do not think that the increase of experiments has increased abuses in connexion with experiments.

4735. I mean simply that they have increased in the same proportion as the experiments themselves?—I do not know that.

4736. The number of useless experiments would probably increase in the same proportion as the number of useful ones, do not you think that that would be natural?—It may be natural, but it does not come into my observation; I would say so at once if it were so, but I have not seen it.

4737. I ask the question because Sir Charles Bell stated that in his time he thought the number of useless experiments performed was a large number, and we have had evidence from an intimate friend of his that to some extent that applies to England, namely to Mayo's experiments. Now, what was true in the time of Sir Charles Bell I suppose would be likely to be true in our own time?—I would say of Sir Charles Bell that what made his great discoveries incomplete was his neglecting to use those means that were necessary to establish them. Consequently, for the confirmation of his discoveries the experiments of other men had to be performed, and those not in England, but abroad. He having a prejudice in that respect, I should not myself regard Sir Charles Bell's statement upon that question as a statement of authority.

4738. You would attach very little authority to it?—I should attach no authority to it whatever on that point.

4739. (*Chairman.*) But if you were to compare Sir Charles Bell and M. Majendie with regard to the subject which we are inquiring into, you would scarcely hold up M. Majendie as the example which it would be desirable we should follow in this country?—I should say that you want a man quite different from either of them, not even between them, I should say much nearer to Sir Charles Bell than to Majendie. I would certainly say this of Majendie, that he was a masculine observer, and there was an object in every experiment that he did, but he was a ruthless repeater of experiments; and, if I may say so, I think one great reason for giving English physiologists the same right to make experiments that they have in France and in Germany, would be that they may set continental nations an example how to produce the same results in a scientific point of view with greater humanity. That has always been the aim of the English experimenter, and when Majendie was doing these ruthless things, Sir Charles Bell was erring in the opposite direction; and I believe it was the opposite polarity induced by the ruthlessness of Majendie which caused the over fastidiousness of Sir Charles Bell.

4740. (*Mr. Hutton.*) Are you acquainted at all with Dr. Mayo's experiments?—Yes.

4741. Do you regard them as useless, or as eminently useful?—They cannot be said to have been great experiments, they were in their way good at the time.

4742. They were justifiable experiments you think?—Certainly.

4743. And you think that all Majendie's were justifiable, only that their repetition was too frequent?—I think that Majendie might have made his experiments with much greater consideration for his animals. I do not think that the idea entered his mind that he had a suffering being under him. Therefore I think he might have made the same experiments with equally great results and with a less amount of suffering, and he repeated them too often; therefore I blame him for two points, not considering his animals, and injuring them too often.

4744. Now you estimate as very few the number of experiments in which material suffering is involved?—Yes.

4745. I suppose you would not deny that the sufferings involved in raising the temperature of animals till they died would be very severe?—That is a question that I happen to have paid a great deal of attention to, and I am not of opinion that it would produce great suffering, and for this reason, that by the time the animal acquires anything like a temperature of 110°, 111°, or 112°, at the outside (it may sometimes get up to 113° or 114°, but we have only one instance of it), the animal becomes unconscious.

4746. The intermediate period is one of great suffering, I suppose?—In the intermediate period the sufferings are not great. We see those cases in wards; the patient springs up to a high temperature within three days or two days, sometimes within six hours, from 102° or 103°, to 109° or 110°, and shows no mark of suffering or pain; he is in delirium, but he never complains of pain.

4747. But surely the difference between raising the temperature of the blood and raising the temperature of the whole air in which they are is very great?—Yes, but you know a hot air bath of 170° is not a matter of suffering.

4748. But it does not raise the temperature of the body to that?—The temperature of the body cannot be the temperature of the air in such a case, or we should die. If you raised the temperature of the body of the animal, it would probably die before it got to 111°. It would simply pass through the stages of a high fever with its delirium just as we do.

4749. Would you say the same of Mangili's experiments on freezing animals to death?—I would say very much the same kind of thing, nothing is more destructive of sensation than cold; and I have again and again told people who have cold hands, "You have got cold hands," and they have said that they had not. The nerves, when they are cold, lose sensibility; the best local anæsthetic that I know is cold; and in fact it is used as an anæsthetic; and one of the most popular anæsthetics for a short time was ether spray applied so as to freeze the surface which it played upon, and then the operator could cut into the frozen part. Therefore those experiments would be the reverse of painful.

4750. Would you say the same of Goltz's experiment of boiling a frog to death?—That is a horrible idea, and I am certainly not going to defend it.

4751. Would you say the same of Chossat's experiments of starving animals to death, that very little suffering was involved in those experiments?—I am very familiar with those experiments; I have been over them again and again, and I would say the very same of them, that there was very little suffering inflicted on the animals by the process of starvation which they were subjected to by Chossat. I would say with regard to those experiments that they were conducted with great care and skill, and with a sincere desire, I am quite sure, to spare as much as he

Mr. F. Sibson, M.D.

3 Nov. 1875.

could the suffering of the animal. He taught us that the withdrawal of food for a certain prolonged period inevitably led to such a lowering of the temperature of the body that the animal would cease to live; and would be incapable of being brought back into life again by food, unless the temperature were again raised. I need not say that that was a practical lesson to us as physicians which pretty nearly every patient we have had to do with has had more or less advantage from. It was considered that one of the greatest lessons that ever was yet given in physiology in relation to the treatment of disease was that lesson which Chossat gave us from the most careful starvation of these animals.

4752. What should you say of the experiment of establishing a biliary fistula not under anæsthetics, and trying the effect on dogs for eight or nine hours under curari?—I shall be very glad indeed to speak of that. I happen to be chairman of the Scientific Grants Committee of the British Medical Association, and we paid the cost of those experiments after they were performed. In my opinion (and I will avow that a physiologist may differ from it), under the influence of wourali after a short time pain is not experienced; and I hope I may now be allowed to say why. I have had an animal 7¼ hours under wourali myself, and brought it to life again. I have had another four hours; at the end of four hours it began to kick, and I then at once put it to death without stopping another moment. I have seen many animals under wourali, and I have made many experiments with it unpublished, but alluded to in publications, and therefore I speak of a subject that I do know. There is no question that under wourali there is complete paralysis of motion. There is no question also that there is no sign of sensation elicited from a limb through which the poison is circulating; but if you tie one of the arteries of the limb, then you may get reflex movements in that limb. Then further, Schiff is of opinion, from his observations, that the wourali poison in large doses not only paralyses the nerves of motion but also the nerves of sensation; that is the most recent view upon the subject, and I am more inclined to hold with that than with the other, although the nerves of motion are those that are strictly paralysed. Then again these animals under wourali lie there for hours subject to its influence. Granted that their sensation is not absolutely lost, but is capable of being roused by an adequate exciting cause, we know that when a person or an animal lies perfectly quiet, without one single movement of life (which a wuralised animal does,) even if there be the power of making that person feel, the whole mind and consciousness and sensibility gradually fades away; and in the course of perhaps eight or ten minutes after a person is in that still state, there would undoubtedly be no feeling whatever at the nervous centre, though there might be the power of rousing a reflex excitation. I would, therefore, on every consideration say that those experiments are perfectly justified, and that the wourali poison (I have thought it carefully over and studied the whole of those experiments as far as I have seen them) did completely annihilate the consciousness of the animal. At the same time that is a matter of my opinion.

4753. You are aware that experiments have been tried on man with wurari and that the effects have been just the opposite, that the suffering has been very great. That has been put in evidence before the Commission?—I decline to accept that.

4754. (*Chairman.*) Your justification of the particular experiments to which your attention was last directed, turns upon your belief that the wurari does in truth take away the sensibility to pain?—It does.

4755. (*Mr. Hutton.*) Since when do you know has it been believed and asserted amongst scientific men that wurari is something of an anæsthetic?—In a very careful lecture of Dr. Brunton's, one of his very valuable lectures on the pathology and treatment of diabetes, he relates Schiff's view as from his own knowledge.

4756. Do you remember the date of the paper?—I will send it down here.

4757. Can you give the date at all?—It is within the last year, but I will send the very paper. (The lecture was published in the British Medical Journal on the 10th of January 1874.)

4758. Has not this discovery been made in a great measure since wurari was treated by others who are opposed to vivisection as a thing that was not an anæsthetic, in fact, has it not been very much a discovery that was *motivé* by the wish to find out that wurari was an anæsthetic?—No, undoubtedly many physiologists practically work wurari and opiates together; that is, they put into the body both an opiate and wurari; and therefore they practically work upon the view which you put forth, namely, that it is possible that there may be pain there. Therefore from that point of view undoubtedly the painful part would not be defensible.

4759. As a matter of fact have not the speculations about the anæsthetic character of wurari all come up since the time to which I refer?—No. Dr. Brunton's edition of Schiff's view was before those experiments were made. I will send you down the journal and you can take it for yourself from the journal.

4760. Now supposing that wurari is in no respect an anæsthetic, would you say that a painful operation, lasting half an hour, and followed by experiments in which the bile ducts are acted on by medicines during eight and a half hours more, would be very painful or not?—I do not think they would be very painful. I am now looking at the experiments as they are, and putting aside the theory. I do not think they would be very painful because the animal would be perfectly at rest; there would be no struggling; the incisions would be made with great ease; the animals mind would be withdrawn from what I would call the domain of attention, and when there is no attention there is no sensation, no sensitiveness, no pain; and I do not believe that under those circumstances the animal would feel in the way that it would feel if it were not under the influence of wurari.

4761. Does it not come to this then, that the wish to find these experiments harmless, induces the judgment of scientific men to decide that experiments, which nothing would induce them to submit to for themselves, are painless when applied to other animals?—I do not at all admit that statement.

4762. (*Mr. Huxley.*) Now about this business of wurari which has come before us several times, I think the wurari question arose some twenty five years ago, did it not?—It was in 1843 (I have the book in my pocket) that I made the experiment which lasted four hours (I do not now speak of the seven hours experiment), and it was published in 1844. At the end of the four hours the animal kicked and I immediately killed it; as soon as it gave a kick I pithed it.

4763. Somewhere about the time I am speaking of Kölliker published his paper on the subject?—Yes, a great deal later than the date I have given; my observations were made long before that.

4764. The time is fixed in my mind because Kölliker's paper attracted my own attention a great deal, and I made a number of experiments on the subject myself. Now, the facts made out at that time were, first, that the administration of wurari prevented the animal from exhibiting any of the ordinary effects of muscular contraction?—Yes.

4765. That is to say that the animal was paralysed?—Yes.

4766. The question then arose to determine what that paralysis meant and how it was brought about, and Kölliker's experiments tended to show that what happened in the case of the administration of wurari was a paralysis of the terminations of the motor nerves?—Yes.

4767. And by certain very ingenious experiments he showed that if you kept the wurari away from one limb of an animal while the rest of the body was exposed to it, the sensory nerves of that side which was poisoned produced an effect upon the unpoisoned limb when they were irritated?—Yes.

4768. So that he drew the conclusion that while wurari affected the terminations of the motor nerves, it did not affect the sensory nerves, and did not affect the reflex centres?—Yes.

4769. But while drawing that conclusion, it is perfectly obvious that the facts which he brought forward could only go so far as to show that there was no serious impediment to the production of reflex action in the spinal cord itself?—Yes.

4770. And those experiments could not show, and were not intended to show whether wurari affected or did not affect the cerebrum, and whether it had any degree of sensation at all?—Yes.

4771. That is to say, it is perfectly conceivable (in fact that there are plenty of cases parallel) that a poison shall not affect the spinal cord sufficiently to prevent reflex action, but that it shall affect the cerebral hemispheres sufficiently to affect conciousness?—Yes.

4772. The common example is alcohol; it is possible for a man to take enough alcohol to make him entirely unconscious, and yet to leave all his reflex action unaffected?—Yes.

4773. Now Claude Bernard published a paper on the subject, and he, if I may venture to say so, jumped to the conclusion that wurari did not affect the cerebral hemispheres?—Yes.

4774. And that is a conclusion for which there is no justification?—Yes.

4775. And Bernard published in the "*Revue de Deux Mondes*" a very striking article in which he went upon this assumption of his, and drew a lively picture, perhaps more worthy of the pen of Victor Hugo than of that of a staid physiologist, of the supposed tortures which an animal under wurari undergoes. You may have seen that article?—I know of it, but I have not myself seen it.

4776. But in point of fact neither Claude Bernard nor anybody else has up to this time had any scientific justification for the conclusion?—That is so.

4777. The matter has therefore stood upon that footing; and if anybody 20 years ago arrived at the conclusion that wurari did not in any way affect sensation, he simply arrived at a conclusion for which he had no basis?—Yes.

4778. And with regard to its being the wish of physiologists to come to the conclusion that it was an anæsthetic, in point of fact there was simply no ground either for the one conclusion or for the opposite conclusion?—Yes.

4779. But it is a matter of fact that many physiologists, as you say, wishing to be on the safe side, have administered opiates while administering curari?—Yes.

4780. Then recently there have been some very ingenious experiments, published by Mr. Yale and others, which rather tend to show on the whole that wurari deadens the spinal cord as a reflex centre?—Yes.

4781. That is all they absolutely prove, and they leave the question of consciousness and unconsciousness untouched?—Yes.

4782. That is very nearly the state of the case now, is it not?—Yes, I should say so.

4783. (*Chairman.*) Do you wish to add anything to your evidence?—Yes; I should like to say that one of the great experimenters, Claude Bernard, having mastered the whole question experimentally of the nervous system, took opium in hand, and its six compounds, morphine, narceine, codeine, narcotine, papaverine, and thebaine; and he showed the exact property of each of these, in what respect each of them was more fatal as a soporific, and more fatal as a convulsant, that is to say, a giver of convulsions, than the others. And since then two physiologists, Dr. Crum-Brown and Dr. Fraser, have given, along with strychnia, the iodide of methyl, with the effect of diluting it 210 times, that is to say, 210 times the dose was required to produce death with the iodide of methyl. They have given brucia in increased doses with iodide of methyl at the rate of sixty fold. The whole of the rest were influenced more or less by it. There is another series of experiments that I think of great importance which have been made by Dr. Rutherford and Dr. M'Kendrick, in which they tried the antagonism between certain poisons with the effect of making out (I shall not go into the whole of the various agents examined) that chloral hydrate was an antagonist to strychnia and certain other substances.

4784. (*Mr. Huxley.*) With regard to the exposure of animals to a gradually increased or gradually diminished temperature, of course when an ordinary person hears that an animal has been exposed to a temperature of 140°, he pictures to himself the sort of pain it would give to his hand to come in contact with a body of a temperature of 140°, and thinks how horribly cruel that is; or on the other hand, when he hears of an animal being frozen to death, he pictures what would happen to himself in coming suddenly in contact with a very cold body. But I understand your contention to be, that if the lowering or raising of the temperature takes place gradually the animal in point of fact never does feel these temperatures; that is to say, it practically dies by the time the temperature comes to 112° or 113°?—Yes.

4785. (*Sir John Karslake.*) In your opinion, in the later stages of starvation, either in the animal or in the human being, is there considerable pain?—I would say that there is then no pain whatever. There can be no pain because the animal is at a temperature at or below 70°, sometimes as low as 65°, or perhaps a little above 70°, when the animal is in the anæsthetic stage; the nerves then have lost consciousness and sensibility.

4786. (*Mr. Hutton.*) That applies to all animals, does it?—Yes.

4787. But as to the earlier stages of starvation, what would you say?—I am not prepared to speak to that; I do not know. There must be some discomfort undoubtedly; at least we feel discomfort; but it is a very slight discomfort, I imagine.

4788. Human beings feel something more than discomfort, do they not, under those circumstances?—I am not aware that they do.

4789. (*Chairman.*) Then do you mean that when sailors are exposed to the process of starvation, from the loss of their vessel, what they go through can only be described as discomfort or inconvenience, and does not merit the name of extreme pain?—I should say so, certainly. In the first pangs of cold, if they get out of warmth into extreme cold, there is pain; but when cold has lasted long enough to act upon and deaden the nerves, then pain ceases.

4790. (*Mr. Huxley.*) You are excluding from your answer the consideration of sufferings from thirst?—Yes.

The witness withdrew.

Mr. JOHN MALLET PURSER, M.D., called in and examined.

Mr. J. M. Purser, M.D.

4791. (*Chairman.*) Are you Professor of Institutes of Medicine in Trinity College, Dublin?—Yes.

4792. We have been told that in giving your lectures you do not find yourself at all impeded in giving the instruction that you wish to give by the fact that the regulations of the University of Dublin do not allow you to exhibit experiments upon living animals, is that so?—It was Professor Haughton who gave that evidence, and that is a mistake. I must explain that I give two courses of instruction in the University of Dublin. I give a course of instruction in practical histology; and in that course I do not

Mr.
J. M. Purser,
M.D.

3 Nov. 1875.

find myself impeded by the regulation in question. I give also a course of physiological lectures, and in that I do find myself considerably impeded by the regulation.

4793. You wish to perform certain experiments in order to show to your pupils certain processes which have been established by former experiments?—Yes, I do.

4794. Are all those capable of being performed under anæsthetics?—By far the greater number of them are.

4795. If you were permitted by the University to make the exhibition of which we have been speaking, provided that you always used anæsthetics, a great part of the difficulty of not being able to convey all the information that you wish to convey would be removed, would it not?—It would.

4796. And you would be satisfied perhaps with that power if it were given to you?—Well, I should be better pleased with it than I am with the condition which prevails at present.

4797. Would what would then remain over which you would still not have had conceded to you be the experiments upon the higher animals?—Partly on the higher animals, and partly on the lower. It is rather hard to say what are "higher animals." You mean, I presume, warm-blooded animals. Some experiments would remain that would probably have to be performed on warm-blooded animals.

4798. Without anæsthetics?—Without anæsthetics.

4799. Would they be experiments involving considerable suffering?—Yes, some of them undoubtedly would.

4799*a*. Then do you contend for the powers of lecturers generally to perform painful operations for demonstrations to students?—Yes, I do.

4800. Now, if you were told that in institutions like the University College, London, and like Guy's Hospital, there was no such want felt, would you think that there was a want which ought to be satisfied in Dublin, when no such want was felt at all in London?—My view is that the matter should be left to the judgment of the professor.

4801. Entirely?—Entirely.

4002. And that if the sentiment of humanity on the part of the public interfered, it would be an undue interference?—I think it would be an undue interference. I do not consider the public a good judge of such matters.

4003. Do you think that the teachers at Guy's Hospital and the teachers at the London University are good judges?—I think they are good judges.

4804. We have been often told that the students would be very much offended if experiments were displayed before them which did inflict considerable pain upon living animals, is that your belief with regard to your students?—I do not believe that if the experiments were performed as they should be, seriously and with a view to the instruction of the students, any right-minded student would be offended.

4805. In short, you give it as your opinion that your own discretion should be the only rule, and that any general sentiment of humanity in the minds of the public at large should be disregarded?—As I said before, I do not consider that the public is a fit judge of these things. The public, in the first place, do not know the way in which these experiments are performed, and in the next place, they do not know the object for which they are performed, and the value of the instruction to be gained from them.

4806. What I want to know is what your contention really is. I want to know whether you contend that in this matter, your own judgment and that alone should be the guide, and that any interference from any sentiment of humanity on the part of the public should be excluded?—I can conceive a case in which a professor would be extremely ill-judged, and perform experiments which were not necessary, and perform them in a way to inflict more suffering than necessary—under those circumstances I think the professor should be cautioned or prevented from so experimenting, but I do not think it is the public who should prevent him.

4807. But if there were some interference by a competent and high authority, would that be disagreeable to you?—It would be very disagreeable to me to think that I required any such interference.

4808. But we must not suppose that you do. I am now putting it in this way: if there were any teaching going on in this country of the character that has now been described, and if it were proposed that some such high authority, as was suggested in the Bill introduced last year in the House of Commons, should be called in to restrain that, would that appear to you to be a hardship?—I consider that it would be a very unsuitable subject for legislation.

4809. Altogether?—Altogether.

4810. In short you are so convinced of the good judgment of the teacher that you think it should be superior to every other consideration?—I think the teachers of physiology are the most competent judges.

4811. (*Lord Winmarleigh.*) How long have you held your present office?—I have been professor in the School of Physic in Ireland for nearly two years; but I was teaching physiology before that in a private school for nearly seven years.

4812. With regard to those to whom you lecture, the students who are before you, have you any reason to believe that while under your instruction they carry out any experiments upon living animals?—No, I am sure they never do.

4813. Supposing any one were to be known to do it, do you think there would be any strong feeling in Dublin against it?—There is a section of the people in Dublin who no doubt would feel very strongly against it.

4814. Supposing you were to ascertain that one of your own students was making an experiment himself, not under your direction, should you take any steps with regard to him?—That is a very hard question to answer in general terms. I would try to find out what the experiment was, and how he was going about it, and I would volunteer my advice and assistance.

4815. But do you think that if even as you suggest the professor should be left entirely to his own judgment as to the necessity of experiments, that professor should have any control given him by legislation or otherwise over the students till they had passed certain examinations?—I would certainly allow no student to perform an experiment in the school, except under the direction of the professor.

4816. You would see no objection to some restrictions being placed upon the students for that object?—I would make it the rule of every school that no student should perform an experiment in the school, except under the direction of the professor, or of some competent person.

4817. That would not include preventing their having the power of making the experiments elsewhere?—I do not think that the school could control that.

4818. You do not see any mode of giving the professor the power of having some control over the students in that respect?—That is a purely imaginary case I think; because I do not think that students are very likely to do it. Students as a rule are not fond of performing experiments.

4819. I am suggesting the propriety of some power being given to prevent these imaginary cases, if they exist?—I do not think you could control students when once they leave the school.

4820. You have no fear whatever that they would need such control?—I have not the very slightest fear; I do not think the case would ever occur, from my knowledge of students, of Irish students at least.

4821. On an average what is the number of students that you are in the habit of giving instruction to?—The students who enter for my lectures vary from about 50 to 60 each year, and I work the practical histological classes in batches of 20 men,

Mr. J. M. Purser, M.D.

3 Nov. 1875.

We have two or three such courses in the year, according to the number of men who enter.

4822. That is at the University of Dublin ?—Yes.

4823. Do you know of any other schools in Ireland ?—Yes, I know all the schools in Dublin.

4824. But all in Ireland ?—There are schools in Belfast, and Cork, and Galway, but I know those schools merely by reputation.

4825. (*Chairman.*) Your objection to legislation upon the subject is founded upon the impression that all professors will be humane, and all students will abstain from experimenting ?—That is my impression, and my impression on that point is so strong that I think that legislation would be quite unnecessary and would do more harm than good.

4826. (*Sir John Karslake.*) Did I rightly understand you to say that you have given private lectures on physiology for many years past ?—I gave lectures in a private school.

4827. In giving lectures in a private school did you use demonstrations upon living animals ?—I did occasionally.

4828. Did you find it essential according to your view that you should demonstrate in that way for the purpose of fully informing those who attended your classes as to that which you wished to illustrate ?—Yes, I think it quite essential to good physiological instruction.

4829. May I ask where you received your education ?—I received my education partly in Dublin and partly in London.

4830. Had you the advantage, if it be an advantage, of seeing any experiments in Dublin when you were *in statu pupillari* ?—I had, but very few.

4831. Was that in a private class or in a public class ?—Not in a private class, but in a private school; in the same school that I lectured in afterwards.

4832. Did you also see experiments in London upon living animals ?—No, I never saw experiments in London; I never studied physiology in London.

4833. Then the only instance in which you have seen experiments upon living animals was during your study in Dublin ?—Yes.

4834. Do the governing body of the university interfere in any active way with the professors to ascertain the character of their lectures and so forth ?—No, there is no spy put upon us; none of the authorities of the university visit our lectures, but of cuorse any of them might come in at any time and, I was told when I joined the school that no vivisections were allowed, and it is put in the calendar as one of the regulations that vivisections are absolutely prohibited, and of course I promised to obey, and I have obeyed.

4835. Do you think, if vivisections were allowed, the supervision of the governing body would have the effect of preventing anything an improper use of them in the school in case the professors were inclined to use improper demonstrations ?—I quite think so.

4836. I understand you, that as far as you know, not only do the pupils in the school not practice these vivisections in their own rooms in private, but that the students in your class do not practise them ?—They do not.

4837. And never have done so ?—And never have done so; I am certain I should have heard of it if they had.

4838. At the time you yourself were a pupil in Dublin, when you say you did see certain demonstrations on living animals, was there any practice existing among the students who were your contemporaries of making experiments in their private rooms ?—No; I never heard of it, and I never performed experiments myself while I was a student.

4839. (*Mr. Huxley.*) I understand that you feel restricted by the regulations of the university in which you occupy a professional chair from performing any vivisection. Will you tell us how you construe that word "vivisection" ?—Vivisection means an experiment on a living animal; of course it means cutting an animal.

4840. But what I want to know rather is the meaning which you attach to the word "living." Is it the meaning of the authorities of the school in which you are professor that you should absolutely cut nothing which has any life in it; or do they mean that you shall not cut anything which has any feeling in it ?—They mean that I shall not cut anything which has any life in it. As I understand it I am not allowed to perform experiments on animals, no matter how insensible they may be rendered to pain by the use of anæsthetics.

4841. That is to say you may not show your class the circulation in the web of a frog's foot, because pinning its toes out would give a little discomfort ?—They would allow me to do that because I asked that particular question; and I do not pin the toes out but tie them; I put a thread round them.

4842. You may inconvenience the frog a little by tying its toes out with the permission of the authorities; but you must not cut the frog's head off and prevent its suffering any pain at all in order to do something else ?—Once the whole animal is killed they allow me to operate upon living tissues. I think they would allow me to cut off the head, and then pinch the toes to show reflex action.

4843. Will they allow you to show Weber's experiment of the influence of the pneumo-gastric upon the heart. That can be done upon a frog which is deprived of its brain, for example ?—I think they would not like that. But I must say that I have not asked all these questions; because I got a peremptory order not to perform any experiments on animals when I came into office; and then when the histological classes were started, and I began to work these subjects, I asked Professor Haughton if I might show the circulation in a frog's foot, and he said certainly, because that did not hurt the frog.

4844. If you can make it plain to the authorities that a frog without its brain, or with its head cut off, does not feel, you might do it if you like ?—I think if I could make that plain to the board they might allow me to do it.

4845. You do not seem to feel quite sure that you could not make it plain to them ?—I think it would be difficult to explain such matters to gentlemen who are uninstructed as to the requirements of physiological teaching.

4846. So that here we have an example of what inspection comes to, even when carried out by a highly educated body of men who do not happen to be physiologists ?—Yes.

4847. But in fact I may take it as your opinion, I suppose, that a frog under the influence of chloroform, or with its brain extirpated, has no more feeling in it than a board ?—I believe it has none.

4848. And in fact a frog under those circumstances, whatever you do to it, feels less than a frog whose toes you tie, because that frog does not feel at all ?—Yes.

4849. So that while you are prohibited from doing that which does not cause inconvenience to the animal, you are allowed to that which does cause a little inconvenience ?—That is my impression.

4850. And this practical experience of what non-scientific inspection comes to rather leads you to entertain a horror of further interference in the same direction, I suppose ?—That is very much my feeling.

4851. (*Chairman.*) With regard to this experiment on the pneumo-gastric, can that be performed on a frog that has been pithed or had its brain extirpated ?—It can.

4852. Is that a useful experiment ?—It is a useful experiment.

4852. It would tend to enlighten and instruct your pupils if it were performed, you think ?—It would.

4854. You have suffered very much in that respect from the prohibition to exhibit experiments you say ?—I have.

4855. And you have never thought it necessary to ask the board whether they would permit you to exhibit this experiment ?—I did not think it neces-

Mr. J. M. Purser, M.D.

3 Nov. 1875.

sary. I thought I understood the feelings of the board so well by their first directions that I did not consider it necessary to ask the question.

4856. But you have told us just now that it could be performed without giving the frog any pain?—Except the pain caused by extirpating its brain.

4857. And your immediate superior, Dr. Haughton, told you, as I understand you, that if you did not give the frog any pain in your experiments, you might perform them?—That I might perform that one experiment which I spoke of.

4858. Had you ever asked him if he would allow you to perform this other one?—I have not.

4859. He is a very scientific person, is he not?—He is undoubtedly.

4860. And there is every probability that if you had thought it worth while to ask the question he would have given you an affirmative answer?—Possibly.

4861. But the inconvenience to which you have been subjected has been so small that you did not think it worth while to ask that question?—The inconvenience is not an inconvenience to me, but an inconvenience to the class.

4862. But you so little regarded the inconvenience to the class that you did not think it worth while to ask Professor Haughton that question?—I did not think it necessary to ask leave to perform every individual experiment?—I expressed my opinion at the time that these experiments were necessary, and that their performance should be left to my judgment, but they said that would not do at all, that they were to be the judges.

4863. (*Mr. Huxley.*) In fact I suppose you considered the intimation you received as an expression of the pleasure of the governing body that you should not do that sort of thing?—Yes.

4864. And you further felt that if you persisted in making applications of the kind you would probably put yourself in a very disagreeable position with regard to them?—I do not think that they would have made my position at all disagreeable. They have always acted towards me with the greatest kindness and courtesy.

4865. I say you would have put yourself in a disagreeable position with regard to them?—I think I should, because I considered that that prohibition at first was the final expression of their wish. And I understood it to mean that I was not to perform any experiments on animals before the class.

4866. (*Chairman.*) I understood you to say that provided the frog was insensible they permitted you to experiment on it; that is to say, that Professor Haughton told you that, provided the frog was insensible, they would allow you to perform the experiments?—No, they do not allow me to perform experiments under the influence of anæsthetics.

4867. But I understood you to say that in a case where one experiment was to be performed in a way that did not hurt the frog, you were told that you might perform it?—That was not a vivisection at all; it is not an experiment in which the animal is hurt in the slightest degree; it is not an experiment in which the animal is cut in the slightest degree, but it is a vivisection to cut off the head of a living animal, if I understand it rightly.

4868. Do you understand that the prohibition under which you labour is a prohibition which prevents your displaying experiments upon animals that have recently been killed?—No, I think they would allow me to perform experiments on animals recently killed.

4869. They would allow you to cut the head off a frog, and then perform experiments on it?—I think they would: but I should consider myself bound to ask permission before performing such experiments.

4870. Then why did you not cut off the head of the frog and then perform this pneumo-gastric experiments on it?—One of the reasons was that when I was lecturing on that subject, it was almost immediately after my appointment, and things were not sufficiently in working order; I had begun to lecture on a subject not much lectured on before. That is the chief reason perhaps.

4871. (*Mr. Huxley.*) I think there has been possible a little misunderstanding in respect of your relations to Dr. Haughton. I understand that he is dean of the school?—He is called registrar of the school.

4872. As such, he is in no sense your official superior, is he?—Well, I should find it very hard to define exactly what his position is with regard to me. He is the person who gives us the orders from the board; he is the spokesman of the board to us.

4873. Your orders and instructions however do not come direct from the board to you, but through Professor Haughton?—Through Professor Haughton. He sends us a printed copy of the resolutions signed by him.

4874. Then if you get a regulation from the board telling you that you are not to experiment on living animals under any circumstances whatever, you look upon that prohibition as absolute?—Certainly.

4875. But you may go to Professor Haughton, and say to him, "Now do you think I am to understand "this in such a way?" And he may reply to you, "Well, I think in this particular case you may;" but that by no means weakens the force of the general prohibition?—That would be the case. I should look to him as the interpreter of the resolutions of the Board.

4876. That is to say, what would be meant by his saying that would be that in this particular case you need not fear any interference, although you had actually committed a breach of the letter of the law?—Yes, that would be it, I think.

4877. Then it is possible that another point of view may have struck you, that a vast deal of pain is inflicted upon animals for various purposes; as, for example, for the castration of lambs, the spaying of sows and so forth; and it may have struck you that legislation which does not in any way interfere with those operations, which cannot be said to be for the good of the animal itself, might in fairness leave the comparatively small inflictions of pain, attributable to physiologists, alone?—That consideration has struck me, and must have struck others very much. Still I could not say that that was an argument against vivisection; two blacks do not make one white.

4878. Certainly not. The case which I put to you was, that if legislation was to take place you would think it fair that such legislation should have a general bearing?—Certainly.

4879. And that if it could be shown that pain was inflicted upon animals for no good purpose, you would allow, I presume, with every right-thinking man, that such a thing ought to be stopped; that if any person inflicted pain upon animals without some good reason, there would be a fair case for interference?—Yes.

4880. But that you would like to be under the same laws as everybody else in that matter?—Yes.

4881. (*Mr. Hutton.*) You have stated that you thought there were some experiments which are very painful on warm-blooded animals, which it would be desirable to use for the purposes of demonstration. Did you ever use any such in the private school in which you were a teacher at one time?—No, I did not.

4882. Could you give us at all any idea to what kind of experiment you referred?—Experiments on the sensitive nerves.

4883. Do you think that experiments showing the functions of the anterior and posterior roots of the nerves would be desirable for demonstration in a class?—I think certain experiments on the sensitive nerves which would involve pain to the animal would be highly advantageous for the class to see; but I think that there would be very few such experiments.

4884. (*Chairman.*) Is there anything further that you wish to say?—The only thing that I have to say is, I think there is an impression abroad that medical

Mr. J. M. Purser, M.D.

3 Nov. 1875.

students are very fond of performing experiments on animals, and that performing experiments on living animals is a very amusing occupation, and a thing which not only all students but all doctors also are very anxious to do. Now my experience is quite the reverse of that; my experience is that as a rule students have no taste whatsoever for such pursuits. The operations are extremely disagreeable to perform, extremely difficult, and extremely expensive; and I think that all those reasons would make students not take to them. Besides that, I think students would not care to perform operations which they did not think themselves competent to perform, and which they did not think that some good would come from; and I am sure that any student in our schools thinking of performing experiments, would come to the professor and take his advice and get his assistance, and, if the professor thought it necessary, do it under his supervision.

4885. (*Mr. Huxley.*) The better instructed students are in the mode of experimentation the less likely they are I suppose to attempt to perform them without due care?—Yes.

4886. (*Mr. Hutton.*) I understand that when you come to the subject of the pneumo-gastric nerve again you think it very probable that you might obtain permission from the authorities to perform that experiment on the decapitated frog, without really infringing the rule of the Board?—I consider the rule of the Board is such that I could not do it without asking their leave. And experiments of the sort on a frog not decapitated but merely anæsthetised I consider the Board would not at all allow me to do.

The witness withdrew.

Mr. Arthur de Noé Walker, M.D., recalled and further examined.

Mr. A. de Noé Walker, M.D.

4887. (*Chairman.*) You were so good as to say that you would prepare a statement derived from published medical journals of foreign countries of examples of experiments, which you wish to bring under the consideration of the Commission. Have you those extracts with you?—Yes, but they are not exclusively from my experience of foreign laboratories. There are one or two done in this country which I shall lay before the Commission.

4888. Will you be so good as to do so?—I will do so at once in the hope of convincing you how urgently legal interference is called for in order to check and control the practice of performing experiments on living animals. The first instance is one I have found in a volume of the West Riding Lunatic Asylum Medical Reports, 1873, wherein the experimenter on the first page thanks the physician of the ayslum for the "liberal supply of pigeons, fowls, "guinea-pigs, rabbits, cats, and dogs," placed at his disposal for experiment. One of the necessary conditions which I have already adverted to for a proper control over experimental researches on living animals is, that the number allowed to each licensed vivisector should be limited. Now although I cannot prove that the "liberal supply" of so many victims placed at the disposal of the experimenter on this occasion, was more than was absolutely necessary, I nevertheless submit that the paragraph forces a disagreeable and painful doubt on the mind. If he had said "a sufficient number," it would have been different; the word "liberal" to me is uncomfortable. In the judgment and conscience of every thoughtful man, whatever his views may be regarding the practice, vivisection entails a great moral responsibility; first, as regards the least possible amount of suffering the poor victims can be made to endure; and secondly, as I have already said, regarding the number submitted to vivisection. I will make two more remarks on these experiments and then leave them. I have already recommended that every licensed experimenter should send in two returns, filled up with certain details I have particularised, in order that the board controlling vivisection may have every means at their disposal for doing this in the most efficient manner. The remark I would myself suggest to the board, had the return of these experiments been submitted to me, would, among other things, have verged on the following particulars. The experimenter appears satisfied that certain emotional and muscular centres are symmetrically placed in the two cerebral hemispheres. (I did not know myself that was doubtful; I thought it was established, but I may be mistaken.) Now I submit that the experimenter ought to have taken the opportunity of ascertaining, without subsequently recurring to other painful experiments, whether contemporaneous "stimulation" of two symmetrical or rather corresponding centres, intensified the phenomena. He should also have endeavoured to ascertain whether one emotional or muscular centre was able to neutralise or disturb another and antagonistic one. The last observation I will make on these experiments relates to an animal which lived five days with the greater part of one of its cerebral hemispheres exposed, during which it gave rise to a fungus. This animal at the end of five days underwent another operation or experiment which caused its death. Now whether this animal ought to have been kept alive five days, and then to have undergone another experiment would be a proper subject for inquiry, if vivisection were under control. Whether the action of the electric current, poured into any portion of the cerebral masses whatever, is likely to be identical, as the experimenter seems to believe, with the emotions and instincts aroused by a natural and ever varying environment, I leave to others to judge; whether, I mean, the electric current, stimulating certain parts of the cerebral masses, is likely to suscitate in the animal the same feeling and the same instincts naturally excited when the external world is acting on it. Before I proceed to advert to other experiments and abuses, I must, as clearly as I can, set forth a general rule neglected or ignored by some experimenters. Every experimenter should bear in mind that the conditions in which an animal is experimented on, as well as the nature and process of the experiment itself, should be as much as possible according to the order of nature, that is to say, that experiments should represent, as nearly as possible, that which may naturally happen to man or beast. If this rule is set aside we shall very often get information that cannot be of much, if any, use to us, or by torturing nature extort a reply that may deceive us. Every experimenter should bear in mind, that we cannot legislate for nature. All that we have to do is to find out what nature's laws are, and not to force nature to tally with our own fancies or our own theories. Now the next experiment I wish to make a few remarks about is the following: Two or three dogs are operated upon for gastric fistula; one or two of them generally die of peretonitis consequent on the operation. Now I may remark that some laboratories very greatly favour that unfortunate result, because the animals are confined in a damp and exposed places. When one case of gastric fistula however was established, the posterior half of a living frog was inserted into the aperture leading to the stomach of the dog, while the anterior half, head and legs, protruded externally, and were fastened there until half the frog was nearly all digested away. The object was to show us this,—the action of the gastric juice on living tissue. As the gastric juice gradually ate away the skin, the nerves, and the muscles, the frog made desperate efforts to escape by moving its anterior extremities very rapidly. (*See* Claude Bernard *Physiologie*, Vol. 2., page 409, 1856.) The first observation I have to make against this and thousands, literally thousands, of experiments

Mr. A. de Noé Walker, M.D.

3 Nov. 1875.

is, that it is not in sufficient harmony with the order of nature; perhaps I could say with more truth that it was against the order of nature. Dogs do not swallow live frogs, and frogs do not jump down into the stomachs of dogs. However we will let that pass; but I think, secondly, a humane experimenter would have been quite satisfied when he had ascertained that the gastric juice had actually commenced to dissolve the common integument, and then removed the frog; that would have been the most humane proceeding, and perfectly sufficient as an experiment. The third objection which I have against this and other similar experiments is this. If he had not allowed habit to harden him he ought to have divided the medula oblongata or spinal cord of the frog, and thus he would have commenced and ended the experiment with precisely the same results, without causing his helpless victim any pain. Fourthly, as he had done the experiment before, and was certain of the results obtained, the repetition of it before his class was wanton and cruel, especially as a verbal account of the whole matter would be perfectly intelligible. This is all I wish to say of this experiment, conducted, in my humble opinion, with a total disregard of the claims of nature on behalf of her creatures. Now I beg leave to say a few words on experiments made chiefly by toxicologists. Some toxicologists are extremely cruel. These experiments are still very numerous, and I think, if I may use the expression, very much overdone, and require, I believe, as much legal control as any other kind of experiments made on living animals. An animal, for example, can be made to inhale a volatile or gaseous poison, and the effects noted. A non-volatile poison may be injected under the skin, into the rectum or into the stomach. These means appear to me to be such as to amply prove the effects of every kind of noxious or innocuous substance. Not content with this, a common practice is to make a solution of the substance, and forcibly inject it down the windpipe of a dog or cat. This causes the animal intense distress for no necessary purpose; for, in the first place, the absorbing and eliminating function of the lungs is well established; secondly, a non-volatile substance cannot be inhaled; and it is cruel, therefore, to make an animal undergo a most distressingly painful experiment, which does not represent that which can occur in the ordinary course of nature, especially as the action of the same poison had already been determined in every other way. The same judgment must, I think, be passed on another somewhat similar experiment. The œsophagus, or gullet, of a dog is exposed by an operation, and a thread is passed round it. A certain substance, for example liver of sulphur (this happens to come in my mind because I saw it) is then forced into his stomach, immediately after which, to prevent the animal vomiting it, the œsophagus is closed by the thread. Anæsthetics are not, of course, used on these occasions, and the dog lives as long as nature can endure the combined effects of the operation and of the poison, coupled with want of food and drink. In this and thousands of similar experiments nature is not fairly or philosophically interrogated, but rather tortured or violated; they represent nothing that can happen in the natural order of things, but rather an artificial and forced condition, from which nothing really practical can be learned. The same may be said of a very great number of experiments consisting in making an incision in the skin, and forcing some deleterious substance into it, or of opening the abdomen, tying a portion of the small intestine in two places, opening the intermediate portion, and then injecting a noxious fluid into it. I think that in neither of these experiments are the natural contingencies of life represented, and I have in vain endeavoured to learn something from these and hundreds of similar experiments performed by toxicologists in this and other countries. (See Christison or Taylor on Poisons, or any work on toxicology.) Perhaps it has been the bluntness of my understanding, or my incapacity to give a practical bearing to what I learn. Sometimes elements of failure in individuals take that form, and it may be so in my case. But I should like the Commission duly to consider the import of this and similar facts, and pass their judgment on them. Mine is, that they betray a wanton and cruel abuse of power in the nature of the experiment, and in the number of the victims experimented on. I am here reminded of another experiment, known to me. A number of rabbits were deprived of food until they ate dead frogs thrown into their hutch. The object of this experiment was to show that herbivorous animals could live on animal food. What use this information may be put to I leave to the judgment of unbiassed minds to determine. (See Schiff, *Physiologie de la Digestive*, vol. 1, page 67.) I know that the rabbits suffered very much before they were induced to eat the dead frogs. An experimenter (see *Medical Times and Gazette*, 3rd August 1861, page 104,) was once lecturing on the effects of poisons in the animal organism. In order to show us, however, that innocuous matter has the power of "disorganizing" animal tissue, he forced half a pint of boiling water into the stomach of a dog. The animal gave evidence immediately, of suffering great pain, vomited blood, and soon died. Another experimenter (see Handbook for the Physiological Laboratory, page 409,) divides the medulla oblongata of a frog and performs the usual series of experiments on the mutilated animal. Finally, in order to prove that a frog with the medulla oblongata divided does not always respond to stimuli, he places it in a basin or trough of water, gradually raises the temperature till the water boils, and the animal of course gradually stiffens and dies, without having made any efforts to escape. Now, to anyone who had not allowed his heart and intellect to get gradually enslaved and carried away by inordinate zeal and culpable indifference to pain, this experiment would be sufficiently conclusive. I do not think it was necessary to institute a comparative one, because the action of boiling water and of heat generally, is practically known to all the world, and boiling water has always but one effect on animals, whether dead or alive. The experimenter, however, thinks all this must be ignored. He therefore takes a sound frog and places it in the basin, with just enough water to cover all but its head. The temperature is then gradually raised up to 20 or 30 centigrade, and of course the animal soon makes desperate efforts to escape from the painful effects of the hot water. Now, I regard every experiment made on living animals, whereof the result is well known and established, as a criminally cruel proceeding. But when horrible pain is inflicted on a vertebrated animal in order not to prove, but simply to bring about, that which is known to all the world, I characterise such proceedings as aimless and useless, and as a wanton and cruel abuse of power. Had opportunities and other circumstances permitted me I would have summoned both these experimenters with hot and boiling water into the nearest police court, where, if I found that there was a law that regarded only cruel but oftimes hard-worked and provoked drovers, I should at least have succeeded in branding the Englishman that scorched the frog and the Frenchman that killed his dog with boiling water, as men who had permitted habit and lack of reflection to deprive them of that which most men hold in some estimation, I mean the feelings of pity and the sense of shame. I have seen much cruelty inflicted on animals from this unreasonable and unreasoning propensity to recur to a comparative experiment when, as in the case I have just adverted to, about the frog, no comparison could on any pretence whatever, be justifiable. A cat from which the glosso-pharyngeal nerves had been excised was once brought before us. Meat saturated with a decoction of colocynth was then placed before it, and after considerable difficulty about it, swallowed some of it. A sound cat was then brought and no coaxing would of course induce it to partake of the food so prepared. All the world would have anticipated that.

Mr. A. de Noé Walker, M.D.

3 Nov. 1875.

The animal was, however, seized by the experimenter and his assistant, and then one of the frightful struggles so common in physiological laboratories commenced. The nauseous and bitter food was forced deep back into its mouth just to show how the poor animal would shake its head and reject the food with a profuse flow of saliva. This animal was cruelly treated and made wretched for nothing. I have taken, I may say, in perfect honesty, no particular pains in the selection of these experiments for the consideration of the Commission, but have selected them chiefly as typical cases of the various ways in which I believe abuses are perpetrated. I must now recur again to the useless and cruel experiment which I adverted to on a previous occasion, as I hope that the Commission will embody it in their proceedings, and bestow their attention to it. Doves or pigeons were totally deprived of food until they dropped from their perch on to the floor. As soon as it was evident that they could neither stand on their feet nor fly, their anterior or posterior extremities were snipped off with a pair of forceps, after which death immediately ensued. The object of this experiment was to show the effects of slight traumatic lesions on an organism attenuated and exhausted from want of food. (See "*Medical Times and Gazette*," August 18th, 1860, page 151.) Here again I must remark, that in my judgment, this experiment performed on a number of pigeons, was aimless, because I believe that not physicians and surgeons only, but every old dame in Europe knows about the combined effects of suffering and starvation, wounds and want, and of hardships and hunger. If this experiment was unnecessary, it was in my opinion aimless, and, if aimless, a cruel abuse of power over nature's creatures who have their particular rights and claims as much as mankind have theirs, even when one powerful race conquers and enslaves another; even slaves have a certain amount of rights, not legal but natural. Another experiment that has lately been made by a German strikes me as against the order of nature, and therefore, as far as my intelligence about physiological experiments goes, is quite aimless and cruel. He forced into the stomach of a certain number of rabbits at various periods, a quantity of Liebig's extract of meat, equivalent to about 700 to 1,200 grammes of fresh meat. This was done to test the nutrient qualities of the extract. They all died and proved nothing. (*See* scientific section of the "*Gazetta d'Italia*," 23rd August 1875). I have said that a proper supervision over animals, either destined for experiment, or of such as had been experimented on, was absolutely necessary, and that a half yearly return should afford ample information on this head. I shall never forget the first time my attention was drawn to the necessity of this. "This rabbit," said the lecturer, "has had the fifth "pair of cranial nerves divided. It will die in four "or five days, but it will not die from the operation, "severe as it is; it will die of hunger," and of hunger it did die. (*See* Claude Bernard, *Système Nerveux*, Vol. 2, 1858, page 101.) But this was not the worst of it in my estimation. Dogs and rabbits were every "season" allowed to die of hunger instead of being killed. Of course everybody can see that the animal could not swallow its food. I have watched them myself masticating food, and to a certain extent able to put it in the back part of the mouth, but it could not be swallowed, and the consequence is that they die of hunger. I did not see the use of that, and I protested at the time against it. I may here say that although after I was fully qualified and had been in practice some years, I went through these things, I had not the least intention of seeing or hearing them to detect abuses or malpractice. I have, since I last came before the Commission, come across a few particulars regarding the experiment made on a frog, and represented in this sketch (*handing it in.*) (*See* Claude Bernard, *Système Nerveux*, October 1st, 1858, page 188.) It appears that the object of treating the animal in this way was to prove the effects of exhaustion on the nervous system. The exhaustion was, as you see, brought about by exposing the two largest nerves, nailing the feet down to a board, and depriving it of food. The various increasing stages of exhaustion were tested by an occasional discharge of the electric current on one of the exposed nerves. I decline myself to criticise this horrible experiment. I feel too much contempt for the experimenter and disgust for experiment. I will, however, observe that if the experimenter had kept the animal in that condition ten minutes, I say ten minutes only longer than any competent judge deemed to be necessary, I would have deprived that man of his position as a lecturer and a teacher of physiology, as one who had forfeited every pretension to assume to himself, I had almost said, nay, I will say it, the sacred office of extorting truth out of the direful agonies of an animal, and as one, moreover, who had trifled with the moral training of the pupils committed to his charge. I do not know whether I need go on, I have a great number more to read, but the Commission must be very tired, and I think I have read enough to prove that abuses do exist which require your serious consideration.

4889. (*Lord Winmarleigh.*) In those remarks that you have made, I did not hear whether you stated whether any, or, if any, how many of those experiments were done under anæsthetics, and how many were without ?—The question of anæsthetics could not be met in that way. For instance, you might cut the throat of a dog and lay the gullet bare under chloroform, and push the substance you wish to test into the stomach, after which, he would live, according to the nature of the operation, a week, or two, three, four, five, or six days in great suffering. Anæsthetics may be used for the operative part, the part that is done with the knife; but the chief amount of suffering comes afterwards. In the experiment of boiling water forced into the stomach, there was no anæsthetic used. Then in the case of the cat, in whose mouth the meat saturated with a decoction of colocynth was forced, there was no chloroform used.

4890. What I want to ascertain is this, that those cases have been brought forward by you without any note attached to each of them as to the use of anæsthetics ?—No reference whatever is made to the use or not of chloroform. If you starve rabbits until they eat meat, you cannot do it with chloroform.

4891. (*Mr. Huxley.*) I should like to ask you two or three questions, really not with a desire of carping at your views, because there is a great deal of what you said with which I should entirely sympathise; but there are one or two questions which I should like to put to you now about that colocynth experiment. Although it is not a nice thing to force colocynth into a cat's throat, yet I suppose we have all had occasion to taste colocynth at some time or other, and you would hardly call that cruel, would you ?—I would characterise it as cruel for this reason. Two cats were brought into the laboratory, one of which had the nerves of taste divided, and unable to taste. As the taste of colocynth, as you very properly remark, is well known to most of us, I assumed that a cat's dislike to it might be equal to that in the human being. To take a cat therefore and forcibly put colocynth into the back part of the throat, to prove that which all the world knows, I call cruel.

4892. Was that really the purpose of the experiment ? The purpose of the experiment was to show the function of the glosso-pharingeal nerve. The experimenter says, "I have two cats; in one of "them the glosso-pharingeal nerves are divided, and "in the other they are not divided; you will observe "that when I give the one colocynth it does not take "it, when I give the other it does;" so that I take it the object of the experiment was not to show that a cat does not like colocynth, which all the world knows, but to show that a cat with the glosso-pharingeal nerves divided had lost, or nearly lost, the sense of taste ?—The impression made upon my mind at the time was that there was no necessity to force colocynth

Mr. A. de Noé Walker M.D.

3 Nov. 1875.

into the mouth, because it rejected it the moment it smelled it. The cat had been starved for some days before, and yet rejected it instantly when its olfactory nerves were affected by it. I thought that quite sufficient. In the next place, I think we can assume that the functions of the glosso-pharingeal nerves of a sound cat would have been instantly stimulated by a decoction of any disagreeable substance like colocynth.

4893. In fact you do not think it was worth while to show what would happen to a sound cat at all?—No.

4894. But granting for a moment that it was worth while to show how the glosso-pharingeal nerves of a sound cat are affected, you could hardly call that a very cruel way of doing it, could you?—We must remember that a cat is a very irritable animal, and to hold a cat down by force, open its jaws by force, and finally force meat saturated with a decoction of colocynth into its mouth, is a cruel thing to do, if not necessary. The cat was made wretched for days after. The impression on my mind was that the comparative effect was not a thing necessary to show.

4895. In fact you would assume that the cat would dislike colocynth?—Yes.

4896. But there might have been a little danger in that assumption as we know cats are very differently affected by certain substances from ourselves. You will doubtless be quite familiar with the very extraordinary effect of valerian on cats?—Yes.

4897. That certainly has not the same effect on the human being as on cats; and it is just possible that the colocynth would have a different effect on cats?—Yes, it is possible, at the same time it is an animal far simpler in its diet than we are; and any nauseous stuff of that sort would much more easily affect it than it would a human being. I would say that the case was possible, not probable; moreover a cat's dislike for colocynth is as natural and as easily perceived as its liking for valerian is natural, and easily perceived, without forcing it into its mouth.

4898. I understood you to speak of that experiment of feeding rabbits upon frogs. Did I understand you to say that that was in your view a cruel experiment?—Yes; I think it was an unnecessary experiment, and therefore I think cruel.

4899. But the two things surely are separate; an experiment may be superfluous, and yet not cruel?—I quite agree with you there, it may be superfluous, and not involve cruelty. So far it was cruel that the animals were obliged to be starved pretty hard before they were induced to eat dead frogs. The cruelty consisted in the starvation.

4900. I remember hearing a number of years ago (I do not know whether the fact is within your knowledge also) and it surprised me very much when I did hear it, that in Norway, where there is a very long winter, and where there are no very large root crops, the people are in the habit of feeding their cows during the winter with a mixture of stock fish and cow dung chopped up together?—Yes, I am aware of that, and have seen cows fed for months on lemons.

4901. By which diet the cows are maintained through the whole winter?—Yes.

4902. Then there was one other point with regard to the experiment which you have described of putting a live frog partly into the stomach of a higher animal and watching it being digested. Now, perhaps I may remark that I entirely agree with you that it would have been very much better if that frog had been previously pithed; but when you speak of that as being contrary to the order of nature, surely I may remind you that the order of nature, so far as frogs are concerned, is that they should be swallowed by birds alive?—Yes.

4903. And therefore they undergo that exact experiment every time they are so. You would not dissent to that, would you?—I would not dissent to that; only the experiment was made with a dog, and I thought it was against the order of nature, because dogs do not naturally eat live animals. Your remark, however, about some birds that eat living frogs, makes me think the experiment was really not necessary at all.

4904. (*Mr. Hutton.*) Your references have been chiefly to Foreign laboratories. Now, have you any reason for thinking that anything like the same extent of painful experimentation goes on in English laboratories?—I may explain the difficulty that I have had in making up my notes. I have made one or two attempts to get into physiological laboratories in this country with the wish of seeing what was going on there; but finding that I could not do this except under false pretences I gave it up; and the more so, as a gentleman of my acquaintance made a personal application to be admitted with the avowed object of seeing what was going on, and he was refused.

4905. Can you tell us to what laboratories that referred?—I should not like to say.

4905*a*. You would rather not?—I would rather not.

4906. But you were known as a physiologist, I suppose?—No; I was known as a physician in practice, and as one who had said and written a good deal against what I deemed to be abuses perpetrated in physiological laboratories.

4907. You have had some experience yourself as a vivisector?—Yes.

4908. Now I am sure you will not object candidly to state to the Commission whether you yourself have experienced any of the hardening effect which vivisection is said to have upon practical physiologists?—I can only repeat, what I have said just now, that nature will not suspend her laws to please me or any particular individual, or any particular theory, and that vivisectors are not exempt from the law of habit. I can bring you two or three cases to prove the hardening effect of habit. An observation, which first brought to my notice the hardening effect of habit, both moral and physical, is this. I used to dine very often with a lecturer on physiology, and one night I found that I could not enjoy either my cigar or my dinner, because the day before we had gone through the laboratory, and I could not get rid of the imploring look of the dogs which hoped for some food every time that they saw a human being, the patient suffering of the fowls, and of the desperate efforts made by some rabbits to allay the pangs of hunger with anything to engage the digestion; and it appeared to me that my friend was indifferent. He had been a vivisector some years; I was a beginner.

4909. That he did not feel that?—No; and I judged from this; I told him the reason why I could not either smoke or enjoy my dinner, and he shrugged his shoulders and smiled. I wish to add that my experience is, that it is impossible to argue the point with most professional vivisectors. They appear to me to ignore everything; they see no kind of abuse, and very often no pain. This is the result of habit and *esprit de corps*, from which no one is exempt, and of which we all must be warned about.

4910. Now, is it your view that demonstrational experiments on living animals should be altogether abolished, or only made when they are under chloroform?—I will answer it in this way; I would abolish demonstrations, and if my son was going through his curriculum as a medical student, I would not allow him to go on if he were to witness demonstrations. Let that suffice for part of your question. The remaining part of your question referring to the use of chloroform I would answer in this way, that if you could guarantee that the animal from beginning to end was unconscious, I could see no objection to its being used for demonstration, and provided the animal was immediately and invariably killed when the demonstration was over.

4911. Did you mean to say in your last examination that the only use of these experiments is for the purposes of diagnosis, and that they are hardly of any use to the physician for the purposes of cure?—What I said and what I meant was this, that the use of physiological knowledge to the physician is that it enables him in many cases to localize the seat of the

Mr. A. de Noé Walker, M.D.

3 Nov. 1875.

disease. I will explain my meaning more by referring to an example brought forward by one of the Commissioners. Take the case of ringworm; my knowledge of the healthy functions of the skin cannot teach me what the cause of ringworm is; but pathology will. Neither will it instruct me as to remedial agents, whereby I may destroy the parasite, but chemistry will. Or take the case of typhoid fever. We have there a rapid and great waste of tissue; we have an ulceration of certain glands; we have the temperature of the body rising to 106 degrees and more; physiological knowledge, that is to say, knowledge of the healthy functions of the human body, cannot explain all these things, nor will it help in the diagnosis. The word "diagnosis" does not simply mean the knowledge whereby disease is localized, but it embraces the cause of the disease, the pathology of the diseases. If I have appeared to be a little undecided in some of my answers it has been from over caution on my part not to allow one truth to displace another, and to endeavour to keep every truth and every science in its proper place, that we may seek and find certain truths where they really can be found. Etiology, pathology, physiology, chemistry, and the action of remedial agents on the healthy human body have all distinct and different truths to reveal to us, and if these things are kept distinct and in the place where nature has placed them herself, I am quite sure that things will go very much easier with the medical student.

4912. (*Chairman.*) Is there anything further that you wish to say?—Nothing more, except to express the satisfaction it will afford me, if the scanty information I have laid before you, will in the smallest measure help you, not only in relieving science of some of the greatest abuses perpetrated in her name, but of sparing many creatures very much pain, and thus dispel also, that which is causing many persons much unhappiness.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Thursday, 4th November 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
Sir J. B. KARSLAKE, M.P.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

Mr. JAMES B. MILLS called in and examined.

Mr. J. B. Mills.

4 Nov. 1875.

4913. (*Chairman.*) You are a veterinary surgeon in the Royal Artillery now at Woolwich?—Yes.

4914. You are aware of a paper which was communicated by you to the Royal Society for the Prevention of Cruelty to Animals, and which has been by them laid before us?—I am.

4915. You went through a college career at Edinburgh?—I did.

4916. Do the veterinary students and the medical students frequently associate for pleasure and for study?—They do.

4917. During your first term were you admitted to any private meetings where experiments were conducted by students alone?—I was.

4918. To how many do you think?—I could not definitely say the exact number.

4919. During the first term to how many were you admitted do you suppose?—Two at least.

4920. Were those private meetings?—Private meetings amongst the students themselves.

4921. Held in their lodgings?—Yes, in their lodgings.

4922. When you became a senior were you introduced to more of them?—Yes, I was.

4923. To a great number?—Yes.

4924. On some of those occasions did you operate yourself?—I did, I am sorry to say.

4925. Were those experiments made to discover any new facts?—No.

4926. What were they for?—Simply to demonstrate things that were perfectly well known to every student almost.

4927. What kind of animals were the subjects of your experiments?—Cats and dogs.

4928. And how were they obtained?—They were either hunted down by means of running after them in the street at night, or sometimes caught by a bait.

4929. Was that a poisoned bait?—It was.

4930. And how were they recovered?—Antidotes were given, and the animals were restored to animation.

4931. Was that a very painful process?—It was.

4932. Now do you consider that those experiments were due to no other motive than idle curiosity and reckless love of experimentation?—Nothing more.

4933. You have got the paper before you that you have signed?—Yes.

4934. Do you undertake to assure the Commission that that paper is only a plain unadorned statement of the facts of which you were witness?—It contains the simple facts.

4935. (*Lord Winmarleigh.*) How long is it since you have given up making experiments on living animals?—Since April 1872, when I obtained my diploma.

4936. Have you any knowledge of what is going on now in that way?—I have a slight knowledge.

4937. What is your belief on the subject?—I consider that a great many unnecessary operations are performed, which entail a considerable amount of cruelty, and no benefit I am confident ever will accrue from them.

4938. You think that is going on now?—I have sufficient evidence to prove that such was going on this last winter session.

4939. Amongst the students?—Yes.

4940. Have you any positive proof of that?—I have from the students there, and those who performed the operations.

4941. (*Chairman.*) Are you prepared to give us the names of the students to whom you refer?—No; I could not do that, because it would be breaking honour with them.

4942. (*Mr. Erichsen.*) Have you any other positive proof, may I ask?—The students were a class of about 70 or 80, and all, I should think, assisted more or less in it.

4943. (*Lord Winmarleigh.*) And you think that that is going on at the present day?—I have not the slightest doubt that it will go on this session again.

4944. To what period do you know positively it did go on?—This last winter session.

4945. When you say "class" you do not mean that

Mr. J. B. Mills.

4 Nov. 1875.

they were in any positive class when they did this?—No; simply that they were students composing the class at the time in the college.

4946. (*Chairman.*) You only mean, if I understand you rightly, that there was a class of 70 or 80 veterinary students, and that some of them performed these experiments?—Yes.

4947. You do not mean that there were 70 or 80 people in one lodging?—No; this last one was done in the college yard.

4948. In public?—In public; in the yard of the college, the quadrangle.

4949. (*Lord Winmarleigh.*) Was there any professor or any person who had authority presiding over these experiments?—Not that I have any knowledge of. The principal, I believe, knew of it.

4950. But while you were there, you did it amongst yourselves without any superior officer of the college having control over you?—Yes, without any control.

4951. Who had charge of getting these animals?—Anyone that could get hold of them.

4952. May I ask you how you know that that is likely to go on again?—Unless there is a stop put to it, it will still go on.

4953. You think it is such a habit that it is sure to go on unless there is some stop put to it?—It is sure to go on unless there is a stop put to it.

4954. For how long a period do you believe that experiments have gone on such as you describe?—I can only speak from my college career and from the evidence that I have got from students who were there this last winter session.

4955. From your communication with your fellow students do you believe that it has been a practice that has been lasting for some time?—It must have been lasting at least for the last five years; because I entered as a student in the session of 1870–1, and I have evidence of it up till this last winter session 1874–5.

4956. Now will you state the nature of the college itself, the governing body, and the people who have control over the students?—The principal, of course, has the sole control over the professors and students; but those experiments are performed quite unknown to any of the professors there.

4957. I thought you said just now that they were known to some authorities?—In this last case I say, which happened last winter session, it was. The subject that was operated on was a horse, and it was bought for the purpose of dissecting. This animal was subjected during a whole week to operations, such as tenotomy and neurotomy and various minor operations.

4958. Were those operations performed under chloroform?—No; no chloroform whatever was given.

4959. Were no anæsthetics given?—No; none whatever.

4960. Were they painful operations?—Very; the animal was cast by means of hobbles.

4961. And were they operations chiefly on the nerves?—Nerves and tendons; and the animal was bled in different parts of the body for the purpose of the students simply demonstrating to each other things that could be learnt in every-day practice.

4962. What is the custom at the college when the operations are performed under the authority of the college?—As a rule where the operation is very painful the animal is supposed to get chloroform.

4963. Always?—Not in every case; but where there is any great pain, or where it is a delicate operation, and one which involves any minute structure, for the purpose of steadiness chloroform is given.

4964. As regards the college these, to which you have been referring, are entirely exceptional cases, and done without the knowledge of the public authorities?—The principal must have known that this subject was within the precincts of the college; because the animal was kept for a whole week and put out into a paddock adjoining the place, and allowed to live or die there, and was subject to those operations during that whole time.

4965. What was the state of the horse during the time that he was out there to all appearance?—It must have been a very poor appearance, because the subjects which they buy are animals bought at a very low price, and fit for nothing else; and this animal was the subject of a disease of the sensitive laminæ of the fore feet.

4966. And were the experiments made more particularly on that part of the animal?—They were made all over I believe.

4967. But you undertake to say that in the college itself, when under proper control, these experiments are only made under anæsthetics, except under very exceptional circumstances?—Operations of all kinds are performed; when there is any very delicate operation or one involving a great deal of pain, they always give chloroform; but in such cases as firing and minor operations they do not as a rule give chloroform.

4968. But experiments for purposes of research are always done under chloroform?—Yes.

4969. (*Sir J. B. Karslake.*) Was or was not that an unintentional answer of yours, "for purposes of research?" Were any experiments upon living animals exhibited for purposes of demonstration or research to the students?—In some cases they are performed for the purpose of demonstration and in some cases they are performed for disease.

4970. I want to know this, were animals bought and operated upon simply for the purpose of exhibition and demonstration?—They were.

4971. In the College?—They were.

4972. That was so when you were a student in the College, was it?—Yes.

4973. Was it done at lectures?—No.

4974. When?—It was done either during the dissecting hours between 10 and 12, or in the afternoon.

4975. Now what animals were operated upon simply for the purposes of demonstration?—Horses and donkeys.

4976. Were those experiments made frequently in the presence of the class?—Not frequently; because there is a great difficulty in getting subjects.

4977. Were they made by the professor or by students under the superintendence of the professor?—Sometimes by the students themselves, and sometimes by the professor.

4978. When they were made by the students were they always made under the superintendence of the professor?—Yes.

4979. And with their knowledge?—Yes, if within the precints of the college.

4980. I am upon that at present; now what number of years were you in attendance upon the college?—I was so in 1870–1, and 1871–2; two sessions.

4981. Were there any other animals operated upon for the purposes of demonstration except donkeys and horses?—Dogs.

4982. Now can you tell me in the first session that you were there, what operations were performed upon those animals?—Lithotomy was performed sometimes.

4983. On what?—On a horse.

4984. Bought for the purpose?—Bought for the purpose of dissecting; and previous to the animal being destroyed for the dissecting room, the operation was performed. The animal was under chloroform.

4985. And was he destroyed immediately afterwards?—He was allowed to live about 12 to 14 hours.

4986. And the effect of the chloroform had passed away before that?—Yes, and the animal lay in a semi-comatose state till he was destroyed.

4987. Was there any repetition of the dose of chloroform to keep him in a comatose state?—No.

4988. Then in your judgment after the operation was performed, and when the effect of the chloroform had passed away, was he suffering severe pain?—He must have been suffering a considerable amount.

4989. Was that operation performed by a professor?—It was.

Mr. J. B. Mills.

4 Nov. 1875.

4990. Will you give me his name ?—I do not know whether that would be right.

4991. There can be no objection if it was done publicly ?—Principal Williams.

4992. That was an operation upon a horse of lithotomy ?—Yes.

4993. In your judgment was it necessary, with the experience and knowledge which you now have, for the purpose of enabling the students to understand the nature of that operation, that it should be performed on a living animal ?—It is a very rare case that lithotomy is performed on the horse ; and when it does get to that extent the disease calculus in the bladder, it is far better to destroy the animal, because if the operation is performed the animal is of very little use afterwards.

4994. That is hardly an answer to my question. I want to know supposing it should be necessary or expedient in the earlier stages of the existence of stone to perform the operation, would the student learn to perform the operation as well from dissection of a dead animal as from the operation upon the living animal ?—Well, I should think he could ; because the animal was as it were dead under the influence of chloroform, and while the animal was actually dead he would be exactly in the same position.

4995. It is the case, is it not, that horses do suffer very much from stone ?—It is not an uncommon disease ; it is not a very rare disease.

4996. That is the first instance you give of an operation upon a living animal, as I understand, for the purposes of demonstration merely ?—Yes, by a professor of the college.

4997. I am talking of those cases entirely now ; what was the next ?—In the next the subject was the opening of the jugular vein and blowing back of blood.

4998. What was that performed on ?—A pony.

4999. Was it for the purpose of destroying the animal ?—I cannot exactly explain the physiological effect, but it was for the purpose of demonstrating some fact which there had been some controversy about.

5000. By whom was that performed ?—By the principal and his assistant.

5001. Principal Williams ?—Yes.

5002. Now was that animal put under chloroform ? —He was not.

5003. What was the effect of the operation ?—The animal staggered for a time and then regained his feet, and then they pinned up the vessel and allowed the animal to live some time before he was destroyed.

5004. Did he seem to suffer pain after the operation had been performed ?—No, not any appreciable pain.

5005. And was the pony bought for the purposes of dissection ?—Yes, it was bought for the purposes of dissection.

5006. Was that in the first session in which you were a student ?—In the first session.

5007. Was there any other operation of the same class performed upon animals in the same way in that session ?—Not that I can remember.

5008. Were any operations performed upon dogs ? —Not that session.

5009. Now let us have the second session ; what was done then ?—A dog was brought into the college for the purpose of being poisoned. This is not exactly a case of vivisection.

5010. He was brought in for the purpose of having poison administered to him ?—Yes.

5011. What was done ?—He got a dose of hydrocyanic acid, that is to say prussic acid.

5012. (*Lord Winmarleigh.*) Was all this under the eye of a professor ?—I cannot say whether the professor saw this.

5013. (*Sir J. B. Karslake.*) This was done in the laboratory or theatre of the college ?—Yes, the dog got the poison in the surgery I believe, or in the dissecting room.

5014. He was brought into the college, as I understand, for the purpose of being poisoned ?—Yes.

5015. Was that with the knowledge of the principal ?—Yes, it was, or with that of his assistant.

5016. Then the dose of prussic acid was administered probably in the surgery, and was he then exhibited to the students ?—He was then dragged up to the dissecting room and allowed to lie there for a time, and ammonia was given to him as an antidote, and they tried to bring the animal to life again as it were, and he showed signs of life ; and then one of the students knocked his brains out.

5017. What was the object of this exhibition, as far as you understood ?—Simply nothing. It was after he got into the dissecting room that this was perpetrated on the animal.

5018. I suppose the professor did not bring the dog into the surgery simply for the purpose of poisoning him ?—He did ; the dog was brought to the college for the purpose of poisoning him.

5019. Was he brought to the college for the purpose of being destroyed ?—Yes.

5020. By the wish of his owner, do you mean ?— By the wish of his owner in all likelihood.

5021. Then having had the dose of prussic acid administered in the surgery he was dragged by somebody up to the dissecting room ?—Yes.

5022. Who dragged him in ?—I cannot say.

5023. Was it with the knowledge of the professor or his assistant ?—The professor might have known that the animal was being taken up to the dissecting room, but I am confident that the professor did not know that the animal was subjected to that fearful cruelty after he got up there.

5024. How many students were there in the dissecting room ?—About 40.

5025. Was it generally agreed that the dog should have a dose of ammonia ?—When they saw the animal was not exactly dead they rushed down and got some ammonia to bring him to life again, and he did partially come to life again.

5026. Did you understand why they brought him to life again, having known that he was brought there for the purpose of being destroyed ?—Simply to satisfy their idle curiosity.

5027. What idle curiosity ? to see if ammonia would have the effect of an antidote ?—Yes.

5028. That was done, as far as you know, without the knowledge of the professors ?—Yes, I am sure they did not know of it.

5029. How long was he kept in this state ?—Ten minutes to a quarter of an hour, I should think.

5030. Before his brains were knocked out ?—Yes.

5031. Was the same principal the head of the college at that time ?—Yes, Principal Williams.

5032. And how many assistants had he ?—He had one, that is to say, one clinical assistant.

5033. One who would be connected with the dissecting room ?—No, there were præsectors chosen from the students besides for that ; for the purpose of demonstrating in anatomy in the dissecting room.

5034. Was there any other instance besides that, in your second year, in which with the assent of the principal and the authorities of the college vivisection was exhibited ?—One case of tenotomy.

5035. On what ?—On a horse.

5036. Was that in the second session ?—Yes.

5037. Was that horse a horse that was bought for the purposes of dissection ?—For the purposes of dissection.

5038. Who operated upon him ?—The principal.

5039. Mr. Williams ?—Yes.

5040. And what was done ?—Tenotomy was performed on the tendons of the near fore leg.

5041. Was the horse put under chloroform for the purpose ?—No.

5042. Under ordinary circumstances, when an operation of that sort was performed upon a horse for the purpose of curing it, would chloroform be administered ?—It would be, as a rule.

5043. You have seen that done ?—No, I have not seen it done, not for the purpose of being of use to the horse.

Mr. J. B. Mills.

4 Nov. 1875.

5044. (*Mr. Erichsen.*) Is there any appreciable pain in tenotomy in a horse ?—Yes.

5045. (*Sir J. B. Karslake.*) Is it anything comparable to the pain of firing a horse ?—It is not comparable to that.

5046. That is extremely painful, I believe, though not dangerous ?—Yes.

5047. As I understand from you chloroform is not administered when a horse is fired ?—In this college it is not.

5048. Do you administer it yourself ?—Yes.

5049. You find it useful ?—Yes.

5050. Is there any difficulty in it ?—None whatever, if done with care.

5051. In your own practice in firing horses do you always administer chloroform, or sometimes not ?—Sometimes not, and sometimes I do, depending entirely upon the extent of the operation. If it is a large surface that has to be fired, as a rule chloroform is given, but if it is a small minor operation, we do not do it.

5052. The minor operation causes considerable pain, does it not ?—Not to the same extent as firing a large surface.

5053. Now may I take it that those were all the experiments exhibited upon living animals, the three which you have mentioned to us, during the time that you were at college ?—They were.

5054. One on a horse and one on a pony in the first session, and this one on a horse in the second ?—Yes.

5055. Now I understood you to say that the experiments that were made in private were made by students in the veterinary college and in the medical college ?—A few of the medical college students were always mixed with the veterinary students.

5056. Did they meet and make arrangements that they would perform these operations ?—Yes.

5057. And you were one of them ?—I was one of the veterinary students, I am sorry to say.

5058. In the first session did you always meet in the same room ?—It depended entirely who had got the animal, and whose lodgings the animal was in.

5059. I infer from what you say that you met in different students' rooms ?—Yes.

5060. Was it the subject of conversation generally among students that these experiments were going on ? The subject of conversation when we were together quietly ; we did not make it a public thing at all.

5061. Did you ever communicate to the professors that you were doing this ?—Never those private experiments.

5062. Did you assume that it would have been distasteful to the professors if you had told them ?—I cannot say.

5063. Did you intentionally keep it secret from the professors ?—We did ; we kept it private from everyon eexcept ourselves.

5064. Was there any arrangement made before him as to what particular operations should be performed on an animal when you had secured one ?—None whatever.

5065. Now take the second session when you were an advanced student, how many operations did you witness do you think altogether ?—Three.

5066. And in the first ?—Two.

5067. That is the whole number ?—Yes.

5068. Was it in the second session that you yourself operated ?—The second session.

5069. What did you do ; had you secured the animal in the first place yourself ?—I secured one of the animals.

5070. Was more than one operated upon on that occasion ?—No, only one.

5071. Then what was the animal upon which you operated, and which you had secured ?—A cat.

5072. How many students were present ?—Six to eight.

5073. And of a mixed class, some veterinary students and some in the medical college ?—Yes, there were two medical students, I know.

5074. What did you do to the cat ?—We opened the thorax.

5075. (*Mr. Hutton.*) Is this the experiment described in the letter read to us by Mr. Colam ?—Something similar to that experiment. That seemed to be the favourite one of all.

5076. (*Sir J. B. Karslake.*) And what was done then ?—It was simply to see the pulsating of the heart.

5077. Was there any particular student (I do not ask his name at the present moment) who suggested the expediency of trying this experiment of opening the thorax ?—It was a general idea with us all.

5078. Do you know where they got the idea from ?—I have not the slightest knowledge, except from reading.

5079. Nobody in the college as far as you know suggested it ?—The students amongst themselves might have suggested it to each other.

5080. Nobody higher in the College suggested it ?—I should think nobody did.

5081. You operated upon the cat ?—Yes.

5082. Not under chloroform ?—Not under chloroform.

5083. What became of the cat ?—The cat died after the operation.

5084. How soon after ?—Seven to eight minutes, that is to say, after the pulsation had ceased.

5085. Was each of the operations, which you have mentioned as performed in the private rooms of the students, an operation of the same class and character, or was there anything else besides cutting the thorax ?—There was the picking up of different blood-vessels and nerves.

5086. How often was that done ?—It was done in two of the subjects.

5087. Was that done also without any suggestion, as far as you know, upon the part of the authorities ?—Yes ; simply to see the course of the nerve, and pick it up with the forceps and cut it across ; anything of that kind, simply for the purpose of dissection.

5088. Now you have told us, have you, all that was done in your time ?—Yes.

5089. And all that you knew of as being done ?—All that I know of.

5090. Were they generally the same set who carried on these operations ?—There would be a slight change the second session ; because there would be some students gone who had passed their examination in the following spring.

5091. And others introduced ?—And others introduced.

5092. Was it a sort of secret society ?—As a rule in a college like that, so many students have a sort of grinding class together, and associate together.

5093. What would be the whole number of students at that time in the two colleges, the medical school and the veterinary school ?—I could not say how many in the medical school ; I have not the slightest idea.

5094. In your own school how many ?—About 80 or 90.

5095. And how many of them in the first session were in the society or group of students which practised this vivisection ?—It would be from four to five, never more.

5096. And two or three of the medical school ?—Generally two medical students, friends of some of the others.

5097. Were the same medical students in the society in the second session, or were they different ?—There was only one in the second session, and he was a different man altogether.

5098. Then the two had gone, and one other man joined your society ?—It was not exactly a society.

5099. I do not use the word "society" except as meaning a vivisecting class, or group, or whatever you choose to call it ?—It was a certain number of students.

5100. Now, as I understand you, as far as you know, during the whole of the two sessions you and your friends or associates were the only persons in the two colleges who practised this sort of inquiry ?—They were all I knew that did.

5101. Now there was the operation which you referred to which was performed, or something which was done in the yard of the college, which you have heard of; last winter I think you said ?—Yes, last winter session.

5102. Was that information communicated to you by letter ?—It was communicated to me verbally.

5103. You decline to give us the name of the gentleman who communicated it to you ?—Yes.

5104. Is the same principal at the college now ?—Yes.

5105. Principal Williams ?—Yes.

5106. Let us just understand, if you please, what you gathered from your friend who communicated the facts to you, was done to this horse. He was a horse who was bought as I understand for the purpose of dissection ?—Yes.

5107. He had numerous experiments tried upon him in the yard of the college ?—The students performed several experiments on him.

5108. I will come to the number and character of them generally by-and-bye. Now, as I understand you, your informant gave you to understand that between whiles the animal was turned out in the paddock ?—Yes, the animal was turned out in the paddock adjoining the college.

5109. And was kept alive altogether for more than a week ?—Yes, more than a week. I can say positively for a week.

5110. I suppose during that time no operation was performed on him for laminated feet ?—Neurotomy, I think, was the first operation performed on him for the purpose of destroying the sensibility of the feet.

5111. That was really, I suppose, to put him out of pain as far as the feet were concerned ?—To see if it would put him out of pain.

5112. Supposing it was inconvenient to the professor to have the animal used in the dissecting room theatre for a time, and he was suffering severely from laminated feet, would it be in the course of business in the college to perform that operation in order to save him from pain in the meantime ?—No, because an animal that would be neurotomised on both fore feet, and especially one suffering from an acute disease, in all probability during the progress of the disease would have the foot sloughing off and different complications in which the disease terminates, which render the animal totally useless.

5113. I understand that; but I mean as a matter of humanity, if the animal was not to be used at once in the dissecting room, when suffering from a severe disease, such as laminitis, is it a means of relieving the pain in the feet to perform this operation of which we are speaking ?—It is a means of relieving pain decidedly.

5114. Supposing then that the professor had had the horse into the college, and did not want to use it for dissection for a week, and he was suffering under a severe affection of the feet, such as laminitis, would it be in the course of the professor's duty to perform this operation to prevent pain in the diseased feet in the meantime ?—Not if the animal is to be kept after the disease has terminated.

5115. I am assuming that he is going to be dissected; would it not relieve him of pain in the meantime ?—It would relieve him of a considerable amount of pain.

5116. It would relieve him of a considerable amount of pain if it was necessary to keep him a week for dissection ?—Yes, it would.

5117. That was the first operation that was performed on that horse ?—Yes.

5118. After the first operation was performed, how many other operations were performed according to your informant's statement before the horse was killed ?—My informant said that tenotomy was performed, and he was bled in different parts of the body, and several other operations, he said.

5119. Now I suppose that the marks of those different operations must have been visible on the body of the animal when he was killed for dissection? —Decidedly so.

5120. Who is intrusted in the Veterinary College with the care of these animals until they are killed for dissection ?—As a rule they are put into the paddock near the college, to graze there until they are required.

5121. Has any one of the authorities of the college the care of them ?—No, simply a groom sees that they do not get away.

5122. Did you hear whether this horse was actually killed and dissected at last ?—It was, after a week's time.

5123. Do you know at all whether there was any other horse suffering from the disease of laminitis at the same time ?—I did not inquire, but I am confident I can prove on this special subject that this was the animal that was operated on.

5124. I only want to know, for the purpose of identifying the animal, whether you are aware whether any other animal suffering from laminitis was in the paddock at the time ?—It would not be likely at that period of the year.

5125. As I understand you this was during the session of the college ?—During the winter session.

5126. So that dissections would be going on and the professors would be delivering their lectures and demonstrating during the time that these operations were being performed on the horse ?—Yes, it was during the session of lectures.

5127. (*Mr. Erichsen.*) What tendon was divided in the operation of tenotomy ?—The perforans and perforatis.

5128. Is tenotomy sometimes not done in laminitis ?—No.

5129. But neurotomy is a merciful method of relieving the animal from pain ?—It is.

5130. And is commonly employed by veterinary surgeons ?—Yes.

5131. And it was consequently not an experiment but a means of relief or cure ?—I am confident it was not so then. It was done by the students to see who could perform the operation best.

5132. The result, however, was relief of pain ?—It did relieve the animal; the animal went sound afterwards.

5133. That experiment was performed in the yard, you say. Is that yard overlooked ?—No.

5134. So that although it is a yard these experiments can be done in it in secret ?—Yes; it is a sort of square, a little bit from Edinburgh, and no houses near it.

5135. Is it in the college itself ?—In the buildings of the new college.

5136. You spoke of a dog having been brought there to be poisoned by the consent or by the wish of of his master, and you said that prussic acid was administered to that animal. Is not the administration of prussic acid about the most merciful means of killing an animal ?—Yes.

5137. There is no pain whatever, so far as you know, either in man or animal, after the administration of prussic acid, is there ?—There is not.

5138. How much prussic acid was given to that dog ?—I could not say the amount.

5139. Does not a very small amount, an amount of a very few drops, of prussic acid destroy an animal ?—A very few drops.

5140. So that it must have been a matter of accident if enough was not given to the animal to kill him ?—A considerable quantity was probably given to the dog, but he would pour out a good deal of it from his mouth.

5141. But even then have you ever seen an animal, into whose mouth a considerable quantity has been poured survive such an operation ?—No.

5142. Have you ever heard of such a thing ?—No.

5143. Will it be in the range of possibility to pour, say a tea-spoonful of prussic acid, into a dog's mouth, and for the dog to eject enough to live afterwards ?—

Mr. J. B. Mills.

4 Nov. 1875.

No; but this particular dog cannot have had enough to cause death.

5144. (*Mr. Hutton.*) Was it diluted?—It was Scheele's prussic acid.

5145. (*Mr. Erichsen.*) About two or three drops of Scheele's prussic acid is enough to kill a man, is it not?—Yes.

5146. And a quarter of a drop will kill a dog, will it not?—No.

5147. How many drops are required?—I do not know the minimum dose.

5148. Scheele's prussic acid is very strong, much stronger than that which is used in medicine?—Yes.

5149. (*Chairman.*) I understood you to point to this, that this particular dog had not had prussic acid enough to destroy life?—Just so.

5150. And as soon as the students found that to be so they seized, I understand, upon him for the purpose of trying upon him an experiment with regard to an antidote?—Yes.

5151. And that experiment with regard to an antidote was an unauthorised experiment, done at the volition of the students themselves?—Yes.

5152. And you consider it to have been a cruel experiment?—Yes.

5153. And you consider that students ought not to have the power of performing a cruel experiment of that sort on their own hook?—Decidedly not.

5154. (*Mr. Erichsen.*) Will you tell me why the administration of an antidote is a cruel experiment?—The administration of this antidote would not have been cruel in itself but for the brutal usage the animal was put to afterwards.

5155. What was that "brutal usage"?—The brains were knocked out with a hammer, the skull was fractured, and the brains protruded.

5156. With regard to these experiments performed on cats in lodgings, I presume that there were other people besides students lodging in the houses in which those experiments were performed?—Only the landlady and her husband, as far as I know.

5157. Did the students occupy the whole of the rest of the house?—There were three students occupied apartments in the house.

5158. And did not the noise, the cries of the cat whose chest was being cut open, disturb the neighbourhood?—Yes, and we actually killed the landlady's cat, and very nearly got into a great deal of trouble about it.

5159. Was no public complaint made?—No public complaint was made, but we were threatened that they would make it public.

5160. Your experience is derived entirely from the proceedings of the Veterinary College at Edinburgh?—Yes.

5161. Not in any way from the Veterinary College in London?—No, I have never been there.

5162. Nor in any way from matters connected with the medical school in Edinburgh?—No, I do not know much about it.

5163. You have never attended the physiological laboratory there?—I have not.

5164. You know nothing of what goes on in the medical schools from your own observation?—Not from my own actual observation.

5165. (*Lord Winmarleigh.*) I think you said that that dog was sent by the owner to the college for the purpose of being destroyed?—Yes.

5166. (*Mr. Erichsen.*) It was a diseased dog I suppose?—I could not say whether the animal was diseased or not. It might have been an old dog, or it might have been doing something wrong.

5167. (*Mr. Hutton.*) I understood you to say, in answer to Sir John Karslake, that you only saw five private experiments in lodgings during the two sessions you were at the college?—Yes, only five.

5168. And I think you said that in none of those cases was there anything like chloroform administered?—No. There was, I think, in the first session.

5169. I read in your letter,—"In a few cases the "animals were narcotised when no suffering was "caused either in the process of poisoning or in the "after experimentations." Do you mean there, narcotised by poisoned bait?—Yes.

5170. You mean that the drug on the bait was a narcotic in some cases?—Yes.

5171. And that in those cases the animal did not suffer?—No; but the majority of cases were done without that.

5172. Do you mean that that applied to two out of five, or three out of five?—It would be about two out of the five in which this was done.

5173. Were you not lecturer on materia medica in this college for a time?—Yes.

5174. That was after the time when you were a student there?—Yes.

5175. Did anything happen of this kind while you were lecturing?—I never heard of anything. Of course I was not then associated with the students privately.

5176. But such a thing as a horse being a week in the yard and being experimented on would have come to your knowledge, I suppose?—It would have done if it had happened; but it was in the summer session that I was lecturing, and the consequence was that they did not dissect then owing to the heat.

5177. You were only lecturing for a single term of three months?—Yes.

5178. And during that time you heard of nothing of the kind?—No.

5179. Did you understand from your informant that in this case of the horse, which occurred last winter, the poor creature suffered a great deal?—Yes, a very great deal.

5180. Did he say which of the experiments were the most painful?—He did not.

5181. (*Chairman.*) You spoke of the four or five students who were associated with yourself for the purpose of experiments. Have you any means of knowing whether you were the only four or five who were associated, or were there other knots of four or five who were associated for the same sort of purpose?—I have not the means at present, but I might have.

5182. You do not know at all?—I did not know at the time.

5183. And do you now know?—I do not.

The witness withdrew.

Mr. W. B. A. Scott, M.D.

Mr. William Benjamin Archibald Scott, M.D., called in and examined.

5184. (*Chairman.*) You are in practice as a physician at Willesden, near London?—Yes.

5185. And you are a doctor of medicine of Edinburgh, and a licentiate of the Royal College of Physicians of Edinburgh, and of the Faculty of Physicians and Surgeons of Glasgow?—Yes.

5186. Have you been in communication, with a view to this inquiry which we are holding, with the Royal Society for the Prevention of Cruelty to Animals, and also with the Society for the Abolition of Vivisection?—I have with Mr. Jesse. I can hardly say that I have been exactly in communication with the Royal Society for the Prevention of Cruelty to Animals. I had a letter from Mr. Colam mentioning that he had mentioned my name to the Commission.

5187. You have taken an interest in the subject which is the subject of our inquiry?—Yes.

5188. Have you any experience in the subject of experiments on living animals?—I have witnessed two or three, and should have witnessed more, only I gave over attendance at a physiological laboratory.

5189. What was the reason of your giving it over?—Because I was disgusted.

5190. And where was it you saw those experi-

Mr. W. B. A. Scott, M.D.

4 Nov. 1875.

ments?—The physiological laboratory I attended was in the University of Edinburgh, in the year 1871.

5191. And were the experiments that you saw during the short time that you attended there of a very painful nature?—I only witnessed one; I left after the first; I shall be happy to describe that.

5192. Will you do so, if you please?—Several frogs were poisoned with curari or wurari, which destroys motor power without destroying or even impairing sensibility (some think it even increases it). In that state their bellies were ripped open, the mesentery sufficiently exposed to be placed on the microscope, still in connexion with the living animal, and a class of certainly not less than 50 or 60, I should say more like 70 or 80 students, each had his turn at one of the microscopes to examine the circulation in the mesentery under the circumstances; the object being, I can hardly say to determine, but to illustrate a point which the professor, Professor Bennett, was very fond of maintaining in opposition to some others, namely, that during the process of inflammation the white cells of the blood did not pass through the walls of the capillaries and form the pus cells, but that the pus cells were formed anew outside the vessels in the extravasated liquor sanguinis. This experiment struck me as the more peculiarly wicked, inasmuch as the professor of pathology stated that in order to witness the extravasation of the cells, which he believed really took place, an examination of a good many hours would be necessary, even in one of the higher animals. Now the time that each one of the students could have examined this frog was certainly not more than two minutes. These creatures cannot have been in pain for less than two hours, including the time of preparation and examinations; and I took especial pains to ask the assistant, Dr. McKendrick, whether any means were adopted to make the animals insensible to pain, and he said he was sorry to say there were not. I thought after that I had had quite enough of it, and I did not attend the class any longer. Then as to the question of curari not rendering the animals insensible to pain, I may state that there is an experiment in a work of the highest authority, by Drs. Klein and Burdon-Sanderson and others, expressly designed to show that very point.

5193. Then speaking from the experience which you have told us, and from your general knowledge with regard to the lectures at Edinburgh, you consider that in respect of frogs the experiments are extremely painful, that no effectual measure is taken to diminish the pain, and that the suffering is very considerable both in its nature and in the duration for which the animal is subjected to it?—I do, and in regard to some other animals still more. I have heard the professor of pathology say that it might be necessary to keep an animal for, I think he must have meant at least 12 hours; not a frog, but a cat or a dog in the same circumstances, to determine a similar question; and in that work by Drs. Burdon-Sanderson and Klein it is mentioned that in watching the process of inflammation in the tongue of a frog it may be necessary to keep the animal alive for 48 hours, and as of course one person cannot examine 48 hours on end, it may be necessary to replace the tongue in the mouth, and have it out again when you wish to examine it.

5194. Have you any observations that you wish to address to the Commission?—I wish to address some observations to the Commission in proof of the assertion that the convenience of the operator and not the comfort of the animal is the sole object consulted, and in order to illustrate that, I would quote from chapter 31 of the "Handbook for the Physiological Laboratory," by Drs. Brunton, Foster, Klein, and Burdon-Sanderson, which is the chapter on "Urari poisoning and independent muscular irritability." The first observation in that chapter is this, "Introduce beneath the skin of the back of a strong frog a drop or two of a solution of urari (the exact strength of the solution and the dose required will depend on the source from which the urari has been obtained). In a short time the frog will be found perfectly motionless with its respiration arrested, but its heart still beating." In many cases respiration is kept up by artificial means. "Lay bare the sciatic nerve in the thigh, slip under it a pair of electrodes connected with an induction coil, and stimulate the nerve with an interrupted current, taking care that there is no escape of the current into the surrounding muscles. This may be effected by slipping under the electrodes a small piece of india-rubber sheeting; if the animal has been thoroughly poisoned, no contractions whatever in the muscles of the leg will follow upon the application of a stimulus, however strong, to the nerve. If contractions do make their appearance the poisoning is not complete; and the student must wait or inject a further quantity of the poison. The nerve having been proved to be insensible to stimuli, lay bare any of the muscles of the leg and apply the electrodes directly to them. Contractions will be manifest upon the application of a very slight stimulus." Then it goes on "the effect of urari is to destroy (or suspend) the irritability of nerves but not that of muscles." Now that expression, though perfectly correct, and not likely to mislead any medical student, might possibly lead non-medical men to suppose that by destroying the irritability of nerves was meant destroying sensory power. However, as you will see in a second it does not mean that, but only means that it destroys the power of conveying a motor impulse. Now I have made this note to that. In all the above not a word is said about giving the poor animal any chloroform, because (and I think this is noteworthy), the urari being injected before the experiment, the animal is from the beginning incapable of writhing in its agonies so as to disturb the operator. In the next observation it is coolly suggested that "a slight dose of chloroform" may be given to the animal during its preparation; why? because as it has not then had any urari, its writhings would interfere with the necessary and exquisitely painful preliminary dissection. The operator's convenience is clearly alone considered. This next observation is expressly designed to show that sensibility remains. "Observation 2.—In a strong frog make an incision through the skin between the ilium and coccyx along the line *k m*, figure 266, cut cautiously through the ileo coccygeal muscle until the peritoneal cavity is reached. The three nerves which go to form the sciatic nerve will come into view when the sides of the wound are held apart. Very cautiously, by means of a small aneurism needle, pass a thread under these nerves, putting it under from the outside, and bringing it out again on the median side. Be very careful not to wound the blood vessels. Repeat the same process on the other side, passing the same thread under the nerves of that side too, but putting it in at the median side and bringing it out at the outside. The thread will now be in the position of the line *o*, *p*, *q*, in figure 266, with the nerves of one side lying over it between *o* and *p*, and those of the other side over it between *p* and *q*." To make this intelligible in the absence of the figure, I may explain that this means that the ligature includes the vessels, but excludes the nerves. "Tie the thread very tightly round the abdomen so as to check entirely the flow of blood to the lower limbs. All this may be done under a slight dose of chloroform." The writhings of the tortured animal would otherwise impede the delicate and intensely painful dissection, since no urari has at this stage been given to paralysec motor power. It would not have done to give curari at this stage, because the object of the experiment is to show the difference in the parts of the system which have received the urari from those which have not. Now if the urari were administered before the arteries have been tied, clearly the limbs, as well as the body, would have received the poison. "The nerves thus form the only means of communication between the hind limbs and the trunk, the vascular communication being entirely stopped. Now inject a small quantity

Mr. W.B.A. Scott, M.D.

4 Nov. 1875.

"of urari into the back and wait until the poison has "had time to produce its effects in that part of the "body to which alone it has access, viz., the part "above the ligature;" and it may be remarked that by this time the anæsthetic effects of the "slight" dose of chloroform, which it is humanely suggested may be given will have passed away. Then the professor goes on, "The following facts may then be determined. "Though there are no voluntary movements in the "body, head, or fore limbs," (those are the parts which have been urarised,) "some slight (voluntary?) "movements may sometimes be witnessed in the hind "limbs. Pinching or otherwise stimulating either "hind foot may produce movements in either one or "both hind limbs, but in no other part of the body. "Pinching or otherwise stimulating the skin of the "head, fore limbs, or trunk above the ligature may "produce movements in the hind limbs but in no "other part of the body;" because all the rest of the body has been curarised and is incapable of movement; and therefore the animal can only show its pain by those limbs that remain uncurarised. "These facts," the professor says, "are intelligible only on the "hypothesis that the urari has destroyed (or sus- "pended) the irritability of the motor nerves in that "part of the body to which, by means of the blood "current, it has had access, but has not destroyed "the irritability of the sensory nerves" (these are the very words of the book) "or of the central nervous "system. Pinching the skin of the fore limb gave "rise to an afferent nervous impulse." Then there is a third observation, merely describing a very painful operation to be performed on the frog, without one word of giving chloroform even during the preparation of the animal. The same remark applies to the fourth observation. I will just read the preparation in the third observation. "In a fresh strong frog lay "bare the sciatic nerve on one side, say the right, in "its lower course, place a ligature under it near "where it divides into its two branches, and tie the "ligature tightly round the leg above the knee. "The circulation of the lower right leg will thus be "completely arrested, but inasmuch as the nerve is "not included in the ligature there will be complete "nervous connection between the right lower leg and "the rest of the body. Poison with urari." There is not a word about giving chloroform there. The fourth observation is:—"In a fresh strong frog, "dissect out a gastrocnemius (or any other single "muscle), dividing both insertion and origin an "ligaturing its blood vessels, thus leaving it connected "with the rest of the body by its nerve only. Poison "the frog with curari." And it is not even said that a "slight dose of chloroform" may be administered. That is the testimony of quite the standard book in England on the subject; a work which in the preface is said to be "intended for beginners," for mere students, to seek a place in the laboratories. And I may just refer to a passage in the same work, page 162, to show the length of time for which animals are sometimes kept in pain. "The tongue is prepared as "for the study of circulation. The mucous membrane "covering the large lymphatic sac of the under "surface is snipped off with curved scissors. The "observation is necessarily tedious, often lasting for "forty-eight hours. It is therefore desirable to "replace the tongue in the mouth for a time after "each examination."

5195. Have you any further observations that you wish to make, about what you have yourself seen?—I once saw a frog poisoned with curari, and the heart exposed to show that there was what the professor called a living heart in a dead body.

5196. But at that time when he called it "a dead body" had the usual precaution been taken to pith the frog or otherwise destroy its sensibility?—Not so far as I am aware.

5197. What did he mean then by calling it a dead body?—He meant that the body was immovable, that the curari had poisoned the motor power, and the feet could not move at all. And frogs used to be handed round, I remember, in the Physiological Lectures in University College, to show the lymphatic circulation. I cannot say positively and distinctly that they had not been narcotised, but I am as sure as that I am sitting here, that nothing was said about it.

5198. Your opinion is that the natural sensitiveness of the frog is such, that experiments ought not to be performed upon it without some preparation to remove that sensitiveness?—I think not even on a frog certainly. But then curari is used with higher animals than frogs; it is used with cats and dogs and guineapigs.

5199. Do you mean that there are instances within your own knowledge of experiments, painful in their nature, made upon cats, dogs, and guineapigs, with no other anæsthetic than curari, if curari is to be supposed to be an anæsthetic?—Well, I can positively say this, that cats and dogs and guineapigs have been subjected to microscopic examination (in just a similar way to that frog I spoke of), in which chloroform or chloral was certainly not administered the whole time, and in which I believe it was only urari that was used, I did not see the experiments myself; but I have heard them referred to by the professor of pathology in Edinburgh.

5200. (*Lord Winmarleigh.*) On what occasion was it that you left the college when experiments were performed that you thought unnecessarily cruel?—I did not leave during the performance of the experiment; I never returned to the lecture afterwards. It was in June 1871.

5201. Was it the cause at the time amongst those who witnessed it of any exhibition of abhorrence?—No, not the slightest. I never knew an operation cause the least abhorrence to a medical student.

5202. It was done by the professor?—And his assistant. I cannot say whether it was positively the professor or his assistant who prepared the frog; I should think probably both.

5203. Was this in a regular course of lectures?—It was not exactly a lecture, because it was instruction in practical physiology in the laboratory.

5204. It was an experiment of research, as I understand you, then?—Well, it might be called one of research, but its value as an experiment of research would be positively nil. It was very well as showing the circulation, which could have been shown in a hundred other ways.

5205. Do you know with what especial object the experiment was performed?—The object was to prove, so far as it did prove, one of the professor's own points. There was a great division of opinion as to whether, in the process of inflammation, the white cells of the blood pass out through the walls of the smaller vessels into the surrounding tissues, becoming the pus cells, or whether the pus cells are altogether formed *de novo* just from the extravasated liquid. Professor Bennett was of opinion that they were a new formation; and he said that if we looked at these frogs we should see that, although this inflammation had been set up in the mesentery, there were no cells passing through the walls of the vessels. But as each student could not by any possibility have looked at the object for more than two minutes, and as the professor of pathology admitted that an examination of several hours was necessary even for the higher animals, it was quite ridiculous to call that an experiment of research; and besides it was not likely that any of the students would have contradicted the theory of the professor.

5206. But would the discovery of such a truth by such an experiment have led to anything material capable of application to the human frame?—Not in the most distant degree in the world. It was a matter of mere curiosity; nobody ever professed that it had the slightest bearing on anything whatever, except as a mere matter of curiosity. It had to do with the general question in dispute, not with the practice of medicine. Some people think that cells can only spring from other cells; other people think that they can be

Mr. *W. B. A. Scott, M.D.*

4 Nov. 1875.

formed anew in a liquid, and Dr. Bennett was of that opinion.

5207. Then may we take it that there is no action in the human body of a similar kind?—There are the cells in the human body similar to those in the frog; but I mean this, that whether you consider with Professor Bennett that in inflammation these pus-cells are formed *de novo*, or whether you consider with some other observers that they are formed, at any rate in part, by the passage of cells through the walls of the vessels, which ever view you take of it, the treatment remains just the same, and it is not a point of the slightest practical importance, and nobody ever pretended that it was.

5208. But is it not one of the objects of research at the present moment to discover what is the origin of inflammation?—It is an object of research, but they have never shown that there is any practical result to be determined from a question of detail like that.

5209. You think that it does not form an element in the consideration of what is the origin of inflammation?—It may in the theoretical determination of the point. I do not say that it has no bearing on the theoretical question, but it certainly has no bearing on treatment.

5210. Was it an experiment that could not safely or under any circumstances have been performed upon the human being?—I do not see how you possibly could perform it on a human being; because as you have got to watch the inflamed tissue for hours and hours you could not expect a human being to submit himself to it.

5211. (*Mr. Erichsen.*) Is there any transparent tissue in the human being where you could perform that experiment?—No.

5212. (*Lord Winmarleigh.*) Do you give us your opinion as a medical man that that experiment was of no use to medical science?—To medical practice, certainly it was of no use. A thing may be of interest in a merely theoretical point of view, and an experiment may have some tendency to elucidate that, but yet it may have no influence in a practical point of view on the mode of treating the disease in which it occurs.

5213. In short I understand you to give your opinion as a medical man that it was a totally useless experiment?—A perfectly useless experiment.

5214. (*Sir J. B. Karslake.*) Do you say that it is at the present moment not established whether these cells do come through the vessels, or whether they are formed entirely outside the vessels?—It is hard to say whether it is established or not. The preponderance of physiologists certainly consider that the cells do pass through the vessels, that is to say Virchow and the leading physiologists do; but the late Professor Bennett and some others had a theory that they did not.

5215. Then may it be taken that even at the present moment the thing is not absolutely established?—I should think not; my own individual opinion is nothing on a subject like that; but there are good authorities on both sides.

5216. Is it your opinion that no advantage whatever to science will be derived from the conclusive establishment one way or the other, of the question whether these cells do pass through the vessels or are formed outside?—Not one particle.

5217. You cannot conceive that it will do any good whatever?—Not only that; but I do not think any of the people who perform the experiment ever maintain such an idea for a moment.

5218. I am asking you whether in your own opinion, supposing it to be conclusively established by experiment one way or the other, it cannot be of the slightest use to science?—Not the most distant.

5219. (*Chairman.*) Supposing it to be of value in the way of original research, would you think that the exhibition of it whilst still unproved to a large assembly of students was a likely way of settling the question?—Certainly not, especially when each student was informed of the professor's opinion beforehand, and could look at it for two minutes only.

5220. (*Mr. Erichsen.*) I suppose in that case it was an experiment of demonstration, not of original research?—Yes, of demonstration.

5221. Dr. Hughes Bennett would never think of performing an experiment of original research in a laboratory in the presence of 60 or 80 students; he would do it quietly by himself. It was an experiment of demonstration, I apprehend, to show the student the nature of the process of inflammation?—Yes.

5222. Is it your opinion that the advance of medical science has no bearing whatever upon medical practice?—I do not say that; I do not say that it has no bearing whatever in certain departments.

5223. But is it possible to say where its bearing upon medical practice ends; is it possible to say that any given advance in medical science may not at some future period have an important bearing upon medical practice?—I should say that using words in their ordinary acceptation, in common parlance, one might say so of an abstract question like that; to say what is inherently possible or impossible I think is very difficult.

5224. I would give as an illustration the discovery of the circulation of the blood; at the time that it was made it was a pure matter of physiological science, was it not?—Yes.

5225. And without the knowledge gained by the discovery of the circulation of the blood, we could not possibly have known how to treat aneurism. The treatment of aneurism was not known at the time, and we could not have known how to treat such a disease as aneurism if we had not had a prior acquaintance with the mechanism of the circulation of the blood; is not that so?—I do not say that the discovery of the circulation of the blood has had no influence on practice.

5226. I think that your statement has been almost entirely confined to a criticism of Dr. Burdon-Sanderson's work which we have already so frequently had before us?—Yes, but perhaps I may mention the reason of that. The editor of the "Echo" was misled by someone into making the assertion that curari was not used in English laboratories, although it might be abroad; and I thought it was important to correct the impression that that might have led to.

5227. And if I understand you rightly you only witnessed in a physiological laboratory the one single experiment that you have mentioned?—Because I left the next day.

5228. You have never consequently worked at physiology in any way whatever?—Personally, certainly not.

5229. So that you have no practical knowledge and no personal knowledge of the working of physiological laboratories, and you have never worked yourself practically at physiology?—Pardon me, I think that I have a very decided knowledge of the working of physiological laboratories, for I have read that handbook.

5230. But of course any non-professional man can form an opinion from that book?—Besides which I have attended lectures on physiology by Professor Sharpey and Professor Bennett, and on pathology, and I have heard the experiments referred to in them.

5231. But those lectures were class lectures, if I understand?—They were.

5232. I am speaking now of the practical working of a physiological laboratory?—But that was referred to in those lectures.

5233. But I am speaking of personal observation, independent of what you have heard from a lecturer or from anybody else, of the working of a physiological laboratory?—The extent of my attendance in a physiological laboratory is what I have described.

5234. The witnessing of this one single experiment?—That was all in the way of vivisection.

5235. (*Mr. Hutton.*) Would there have been any difficulty in etherising or chloroforming the frog, and still exhibiting the same experiment, if it were a

Mr. W. B. A. Scott, M.D.

4 Nov. 1875.

desirable experiment to see; would that have been inconsistent with exhibiting it?—It would have been a difficult thing to keep the animal perhaps under chloroform quite so long. And another thing is that the curari certainly ensures greater immobility.

5236. But could not ether have been used with the curari?—I do not know whether it could have been or not, but it was not; because I took the pains to ask the assistant that question.

5237. You studied at Edinburgh, I think you said?—At Edinburgh and in London.

5238. Have you any knowledge at all as to whether the practice of vivisection goes on amongst the students at either of those universities?—Yes; among the students in their own rooms.

5239. Could you give us any personal evidence of that sort?—Only what I have heard them mention themselves. I never went to assist.

5240. You heard that as a matter of common conversation at the time?—Yes.

5241. Was that in Edinburgh or London, or both?—In Edinburgh certainly; in London I think. There was one whom I remember at the present moment at Edinburgh; he used to speak of vivisection on frogs which he performed in his own room.

5242. But you do not remember any cases of vivisection on higher animals than frogs, on cats or dogs, for instance, performed by the students amongst themselves?—No; beyond general report I could not name an instance.

5243. But you could name an instance, though you would prefer not to give the name, of a student who practised these experiments on frogs in his own room?—Yes.

5244. And you are not sure what the practice was at University College?—I am as sure as I could be of anything; I know perfectly well that it is a common thing where students are zealous.

5245. Do you apply that to University College?—To any college.

5246. Your impression is that it is a common thing in all colleges?—Among zealous students, not among idle ones.

5247. (*Mr. Erichsen.*) Consequently it is in the pursuit of science that it is done, and not as a matter of idle curiosity, or amusement, or cruelty?—The pursuit of science is one name to give it.

5248. The supposed pursuit of science we may say?—Or of notoriety.

5249. (*Lord Winmarleigh.*) What did you mean then by saying "zealous students"?—Those anxious to get medals and scholarships, and so forth, and those anxious to get themselves mentioned favourably in professional periodicals.

5250. (*Mr. Erichsen.*) Could you give the name of any one student at University College who practises in his own rooms?—No.

5251. (*Chairman.*) Have you any further observations which you wish to make?—I think not.

The witness withdrew.

Mr. W. Legg, M.D.

Mr. WICKHAM LEGG, M.D., called in and examined.

5252. (*Chairman.*) Are you demonstrator of morbid anatomy at St. Bartholomew's Hospital?—Yes.

5253. In that capacity have you tried experiments upon living animals?—I have made experiments, but not in the capacity of demonstrator of morbid anatomy.

5254. Have you tried those experiments at St. Bartholomew's Hospital?—In the hospital itself.

5255. I may take it then that you are familiar with the subject which has been referred to us?—Yes, in some degree. I do not suppose that I have performed more than four or five series of experiments altogether; I do not mean individual experiments, but series of experiments.

5256. (*Mr. Hutton.*) You made some experiments on cats, did you not?—Yes.

5257. Were they performed in St. Bartholemew's Hospital or in a private laboratory?—I do not quite know how to express it. There is no physiological laboratory, that can be so called, at St. Bartholomew's Hospital. The laboratory which we have there is a private room belonging to the lecturer on materia medica.

5258. This was a private room of Dr. Brunton's, was it not?—A private room of Dr. Brunton's.

5259. This series of experiments that I have got, mentioned in the ninth volume of the Hospital Reports, was a series on the effect of the ligature of the bile ducts, was it not?—Yes.

5260. Did that series result in the establishing of any new fact not previously known with regard to the effect of these changes on the bile duct?—Undoubtedly.

5261. Were those experiments made anterior or posterior to the experiments on which this manual or handbook edited by Dr. Burdon-Sanderson is founded?—I cannot answer that question; I do not know the date of that publication.

5262. Dr. Burdon-Sanderson's manual was published in 1873, and your paper was also?—The observations themselves were made in the spring. The St. Bartholomew's Hospital Reports were published in October 1873, and my experiments were made in the January and February of the same year, 1873.

5263. Then I suppose this handbook, which was published I think early in the year, was founded on experiments anterior to yours probably, was it not?—I do not know; of course that would be matter of date.

5264. Is that book familiar to you?—I have a copy, and I consult it whenever I wish for information; but I cannot say that I am very well acquainted with it.

5265. Was it in your opinion necessary to operate on so many as 16 cats to ascertain these facts?—Yes, because the facts got out were quite new, such as were unknown I think to anybody before; and of course to demonstrate with anything approaching to truth you must have a large number of observations to make your induction from.

5266. You mean that simply on the doctrine of averages you would want to verify the thing in a considerable number of cases?—Yes, just so.

5267. Would sixteen be enough for such a purpose as that?—I do not know about the doctrine of averages; it commends itself to my mind that that number would be enough.

5268. Now do you think that the cats in this series of experiments were all destroyed as soon as they might have been for the purposes of the experiment; they were allowed to die, were they not?—No, not all.

5269. I think there is hardly any case in which they were not?—You will find, I think, there are two such cases, the last two experiments but one.

5270. But mostly I find they linger for various periods, sometimes for eight, ten, seventeen, and twenty-three days; they linger during a period in which they appear to have been very much diseased. I suppose they were all very much diseased as the result of the operation—Undoubtedly.

5271. Were the diseases which were the result of the operation of a painful kind or not, do you suppose?—Judging from what we see in man, jaundice is not a painful disease; on the contrary, it is attended with a considerable tendency to sleep.

5272. I have had the jaundice, and it struck me as the most painful period of my life; there was sickness with it?—It depends altogether on the kind of jaundice; these animals are not sick.

5273. Do you suppose that they have not the sen-

Mr. W. Legg, M.D.

4 Nov. 1875.

sation of sickness although they do not actually vomit?—I cannot tell.

5274. Does it not seem to you that in some cases these cats were rather neglected during their last days. For instance, I find that in one case the cat was said to have been found dead something like four days I think after you believed that he died. Does not that look like a kind of neglect on the part of subordinates?—No; the animal escaped from the room in which it was kept and could not be found.

5275. And when it was found it had been dead apparently for some time, and was in a state of decomposition, was it not?—Yes.

5276. But now take one or two individual cases. At page 170 I find this; Experiment 11:—Black tom cat weighing 6 lbs. and 1¼ ozs. operated on January the 9th. It died on January the 25th. Weight only 3 lbs. 7½ ozs. That is to say it lived about 16 days, wasting all the time. Do you consider that that kind of wasting is a painful thing to an animal?—I should think not from what we see in man. Of course we can only judge from what we see in man.

5277. Would it not have been possible with the same result to kill a great many of these cats after they had the disease three or four days?—No; that last experiment that you are speaking of was perhaps one of the most instructive cases which I came across in my experiments.

5278. The cat must have suffered very badly I suppose?—I doubt if it did.

5279. You speak of "the gall bladder being immensely distended; it is over 75 millimetres in length; it is full of green bile. The ducts outside the liver much enlarged; so also those inside, but they are filled with a thick, almost colourless mucus." All that I suppose implies considerable suffering?—Not judging from what we see in men. You see men in the same state who complain of no pain during the whole of the illness.

5280. And do you mean that men die very much in that state and without any amount of suffering?—Without any amount of suffering expressed by the patient.

5281. Take this case at page 175.—"Experiment 16, June 27. Black and white cat, well nourished, full grown; bile duct tied double and piece cut out. July 3rd. As the cat was now very weak and seemed about to die, it was determined to make the diabetic puncture. The cat was therefore laid prone, a cut made through the skin over the occipital protuberance, and the chisel applied immediately underneath this." Now is that puncture a painful operation in itself, or was it performed under chloroform?—It was performed under chloroform, and I doubt whether it be painful, because as soon as it comes out of the chloroform it lies in a helpless state and does not move at all; nor does it give any signs of feeling.

5282. Then the cat lived for two days longer and you examined it to see the result. Now do you suppose that a new experiment, made on a cat already so diseased as that was, would yield a pure result, that is to say, a result not confused by the other causes acting upon it?—That is just what I desired to have, the experiment confused with the disease.

5283. You wished to see what the effect of diabetic puncture would be on a diseased animal as distinct from a healthy animal?—Yes, that is just what I wished to see.

5284. Do not the two results, that you appear to have established by these experiments, open a great many more problems than they solve? The one is the increase of the connective tissue in the liver of these animals, and the other is that glycogen is not produced after ligature of the bile duct. Those are the two main results, are they not?—Yes.

5285. Now do you not consider that they open a great many more problems than they close, and that they involve the further sacrifice of an indefinite number of cats in order to solve those problems?—That may be said of all increase of knowledge; I consider that these are two very important points to be established.

5286. I find in this manual of Dr. Burdon-Sanderson's, at least in regard of connective tissue, and I think also in regard of the other point, that both those results were regarded as established when the manual was published. Were they new to you when you performed them?—Yes. It is my custom before performing any experiment to see the state of knowledge on the subject. In fact before undertaking any research I make myself acquainted with everything that has been written on the subject: and I am quite unacquainted with any researches which establish points similar to those which I have established.

5287. As to the treatment of the cats, who was it that looked after the cats while they were under this treatment?—I looked after them myself, I did not feed them myself, though I used occasionally to do that; but I went to see them always every morning.

5288. There was an uncertainty it seems about the time when several of them died?—I did not go down on Sundays you must remember.

5289. And is that the only cause of uncertainty except in the case of the cat which escaped?—Yes, I believe that is the only cause of uncertainty.

5290. Then in your own opinion these experiments were all necessary—they were none too many?—I think not.

5291. And they were as mercifully performed as they possibly could be, you think?—I believe so.

5292. And that the results established were new and very important?—Yes.

5293. Have you been associated with Dr. Brunton in any other considerable series of inquiries?—No, I have never done any work with Dr. Brunton at all.

5294. This work was only performed in his room, not with him?—Not with him; he knew what I was going to do and the outcome of my experiments.

5295. What were the other series of experiments?—Some experiments upon the anatomical changes in fever which I published I think a year after.

5296. What was the nature of those experiments?—The object was to investigate the changes which occur in the internal organs when the temperature of the body is artificially raised. Fever is simply (we all know the old definition) *calor præter naturam*, and the experiment brought on a state quite like that of fever.

5297. You raised the temperature of certain animals until the point at which they died, I suppose?—No, I kept them for various numbers of hours, some six, some as much as nine; but the animals were all anæsthetised with chloral during the experiment.

5298. So that they were really not suffering at all?—Not at all.

5299. They were under chloral hydrate do you mean?—Yes.

5300. And were they killed?—They were killed at the end of the experiment.

5301. That was the second series, and that was on the temperature of the body, as I understand you. Would you mind telling us how many animals were used in that series?—Four I think in that series.

5302. Were they rabbits?—One was a rabbit, I think, and the other three were guinea pigs.

5303. Then can you tell us what the third series of experiments was?—Some experiments to investigate the action of a new substance, which was discovered by Dr. Matthiessen in his chemical laboratory. Dr. Matthiessen considered that this new substance might be useful as a remedy in medicine, and he asked me to investigate its action; and I investigated it upon dogs and upon myself.

5304. What was the drug?—It was the hydrochlorate of cotarnamic acid; it is a derivative from narcotine.

5305. Is it a narcotic?—No, it is not a narcotic. It turned out to be a very peculiar poison. My experiments were brought to an end by Dr. Matthiessen's sudden death.

Mr. W. Legg, M.D.

4 Nov. 1875.

5306. Did you suffer from it much yourself?—It was a very disagreeable process, I assure you.

5307. What sort of result did it produce?—When injected under the skin it caused a very active inflammation; I injected some of it under the skin of my arm, and I had no sleep for two or three nights.

5308. Was the number of animals large, besides yourself, which you experimented upon in that series?—No; only three or four dogs, I think.

5309. Now that accounts for the third series; what was the fourth series?—On the inoculation of cancer. The animals were chloralised, and then a piece of newly cut-out tumour still warm was introduced under their skin; then the skin was drawn together with a ligature, and the animals allowed to live. In none of those cases was the inoculation successful. They lived three or four months, and at the end of that time they were killed, and there was nothing found.

5310. The inoculation produced no effect?—No. That experiment had never been performed before.

5311. Those experiments, where any serious suffering was caused, were all performed under chloral, as I understand, and the suffering from the wound after the recovery, I suppose, was immaterial?—It would not be very great.

5312. What was the last series?—Upon the cause of the appearance of bile pigments in the urine. Four animals were used in that experiment, and they were under chloroform at the time of the operation and during the experiment, and they were killed afterwards.

5313. So that really the only important series was this cat series; I mean that the only one in which you have used a considerable number of animals was this 16 cat series?—Yes.

5314. (*Sir J. B. Karslake.*) Why were the dogs in the fourth series killed; you had kept them, as I understand, for some time to see whether cancer was communicated?—You could not judge if it were communicated unless you saw the internal organs.

5315. Did I rightly understand you to say that you lectured at all at St. Bartholomew's Hospital?—I do not give regular lectures. It is my custom to demonstrate upon the results of the postmortem examinations.

5316. Do you use vivisection for that purpose occasionally?—Never.

5317. (*Mr. Erichsen.*) You demonstrate in the dead house?—Yes.

5318. (*Sir J. B. Karslake.*) Do you know anything about the regulations as to bringing in live animals at St. Bartholomew's, or the mode in which they are procured. Are there any regulations existing on the subject?—I know nothing of that; I never inquired into that point.

5319. You do not know of any printed or written regulations on the subject?—I never heard of any.

5320. (*Mr. Erichsen.*) Your experiments have chiefly been of a pathological or therapeutic character, rather than of a strictly scientific physiological nature?—Yes.

5321. They have all been conducted, I presume, with a direct bearing on the elucidation of some point in practice or in treatment; some point, at all events, connected with disease that may occur in the human subject?—Yes.

5322. Is it the case that those experiments, to which special attention has been directed, on the biliary secretion, were performed with a view of elucidating morbid conditions that do occur in the human subject?—Yes, certainly.

5323. There is a great difference of opinion, is there not, still amongst physiologists as to the various points connected with the biliary secretion?—Yes; and it seems to me that it is a most important subject in its present state to be worked at.

5324. We all know that diseases of the liver are amongst the most common that occur in the human subject?—And jaundice is certainly one of the most obscure that exists.

5325. And is it your opinion then that we may possibly arrive at some elucidation, or some true knowledge as to the real nature of diseases of the liver and of jaundice by making experiments upon the lower animals?—I have no doubt whatever of that. I think it is a most important means of research; because in the case of animals you may give them the disease and kill them at divers points in the progress of the disorder, which cannot be done with man. When a man dies, you find in his body nothing but the débris of the disease; you do not find the disease actively progressing as you do in animals which you have killed.

5326. I suppose we may take it that you find in the dead-house a condition of things incompatible with life?—Yes.

5327. But you do not find in the dead-house that condition of disease that is still compatible with life, and that is still in a curable state?—Just so.

5328. In order to discover a disease at that period of its existence when it is still amenable to treatment you must do something more than examine the body of a man who died from that disease, when it has passed beyond the reach of treatment?—Yes, that is precisely the case.

5329. I presume then we may take it that it is only by performing these pathological experiments, and, as you say, destroying animals at different periods of the disease, that you can arrive at the knowledge of what one may term the natural history of the disease, the progress of it *ab initio* to the time of fatal termination?—Yes.

5330. And did you perform these experiments with such an object as that in your mind, or were they performed at hap-hazard, or at random, without any very definite idea?—My object certainly was to make out the causes and nature of the disease which I gave to the animals. They were not performed at hap-hazard or at random.

5331. So far as you are in the habit of experimenting, do you, whenever practicable, employ anæsthetics in your experiments?—Invariably.

5332. So that you do not put the animal to any more pain than is absolutely necessary for the elucidation of the experiment; I mean in the progress of the diseased action?—Just so. Of course the first inoculation or communication of the disease to the animal can very often be done under anæsthetics and without the animal suffering any pain that we know of; but the further progress of the disease must be attended with whatever pain the disease may bring with it.

5333. With that condition of physical discomfort, pain or *malaise*, which the disease itself may entail?—Yes, I would like to observe that disease is the common inheritance of all of us, and that unless accident ends his days, every living creature must die of disease, and that disease itself is not of necessity painful.

5334. And you think that the same condition of things is found in animals that are artificially diseased?—Yes.

5335. We have been told that certain diseases induced in animals are productive of great pain to the animals, such for instance as the artificial production of tuberculosis. Now is it your opinion as a hospital physician that tubercle in man is a painful disease when existing in the internal organs?—It depends a great deal upon the organ which is affected; in the substance of the brain I think it is painless, and in the kidneys, spleen, and liver.

5336. I am speaking of the internal organs?—Yes, I should say quite painless there.

5337. And it is reasonable to suppose that it is the same in animals?—Yes.

5338. (*Sir J. B. Karslake.*) With reference to your answer that it is painless in the brain, are there not cases where a great deal of pain is caused by tubercle?—Yes, there are such cases, but tubercular meningitis is seen without sometimes.

5339. (*Mr. Hutton.*) I want to know whether it is not true that these surgically induced diseases offer rather doubtful analogies to the naturally induced diseases. What I mean is that this jaundice for in-

Mr. W. Legg, M.D.

4 Nov. 1875.

stance, induced by a surgical operation, would be probably very different in its course and results from jaundice induced as it is in the human subject?—I do not see the least difference in the conditions of the two states. I think that a ligature put round the bile duct produces the same result as a tumour pressing on it.

5340. Do you not think that the pain inflicted in the operation would very much affect the general conditions in the patient?—I think not.

5341. You think that what jaundice means in the human patient is some ligature of the bile duct?—Yes.

5342. (*Chairman.*) You have told us that all your experiments have been performed under anæsthetics?—Yes.

5343. In short, we may take it that the animals have been treated with as much tenderness as the object of the experiment permitted?—Certainly.

5344. It is your belief that that is the habit of those who perform these experiments generally in this country?—I believe it.

5345. And that at any rate it ought to be?—It should be, and my belief is that it is their custom.

The witness withdrew.

Mr. Arthur Gamgee, M.D., called in and examined.

Mr. A. Gamgee, M.D.

5346. (*Chairman.*) I think you are a doctor of medicine, and a Fellow of the Royal Society?—I am.

5347. And the Brackenbury professor of physiology and histology in Owens College, Manchester?—I am.

5348. And examiner in physiology in the University of Edinburgh?—Yes.

5349. And examiner in forensic medicine in the University of London?—Yes.

5350. I think we may take it for granted that you are familiar with the subject referred to us for consideration?—I believe myself to be so.

5351. Do you consider experiments upon living animals to be necessary for the progress of science and the improved application of medical and surgical science to the human subject?—I do very distinctly think so.

5352. Are you prepared to illustrate that opinion?—I think it is not a difficult thing to illustrate the opinion. Perhaps the statements I am going to make are merely the expression of my own opinion, but it appears to me that there is no department of physiology, no even very limited branch of physiology, in which the most valuable facts have not been determined by experiments performed on living animals.

5353. Are those experiments performed at Owens College, Manchester?—They are.

5354. Are they performed with all the tenderness of which each case admits?—Certainly.

5355. Are they generally for original research, or are most of them for demonstration to the students?—If I might be allowed to do so, I shall give a short account of the mode in which the teaching of physiology is conducted in Owens College.

5356. Will you do so, if you please?—As professor of physiology in Owens College I deliver two courses of lectures. The first is a course of lectures on systematic physiology, and is intended for the instruction of junior or first year medical students. It is a course in which lectures are delivered every day, and these lectures are abundantly illustrated, but as a rule only by the aid of diagrams or models or microscopic preparations, though occasionally some experiments are performed on living animals; never, however, unless the animal has been rendered insensible by the use of anæsthetics. I deliver a second course of lectures, or I carry on a second course of instruction in practical or experimental physiology and histology. The lectures which I deliver in this course are intended for second-year students, and the course of instruction consists in lectures which are delivered twice weekly, and in demonstrations given in the laboratory. The demonstrations in the laboratory are confined, I may say, entirely to histology, and the students there individually examine the tissues of human and animal bodies. In my bi-weekly lectures in the lecture room I illustrate, generally by experiments upon living animals, all the great facts of physiology. I try as far as possible to make my students acquainted with every method of investigation which is pursued by the physiologist, always taking care that no pain is inflicted. In no case, I believe, since my appointment to the chair of physiology in Owens College, has any pain been inflicted for the purpose of demonstration in my class. As a general rule the animal is subjected to the action of anæsthetics, the experiment is then performed, and the animal is destroyed before it has had time to recover from its condition of insensibility.

5357. And I may take it to be your decided opinion, as shown by your practice, that all experiments upon living animals for the purpose of demonstration to students may be made without inflicting any pain upon the animals experimented on?—I believe without exception. There are certainly some experiments which might be instructive, but which entail a great amount of animal suffering, and I think they may therefore well be omitted from a course which is otherwise abundantly illustrated.

5358. Now, speaking of original research, most of the experiments that need be performed for the purpose of original research may be done while the animal is perfectly insensible, may they not?—The great majority, although there are, of course, numerous exceptions.

5359. Of those numerous exceptions another portion will consist, will it not, of experiments where the most painful part may be done upon the insensible animal, and only the watching afterwards be the subject of any pain to the animal?—Certainly. The experiments to which I chiefly referred as not admitting of the use of anæsthetics were experiments conducted to discover the action of drugs. In these experiments it would appear difficult often to employ an anæsthetic without complicating the action of the substance under investigation.

5360. But speaking first of that kind of experiment in which the action of the knife inflicts the pain, you agree in the tenor of the question?—Clearly.

5361. Coming then to another class, that where poison is to be tested, it is evidently impossible to do that without letting the animal suffer the pain of the poison. That, however, is limited to original research?—Yes, clearly. It is not the pain which is the object of investigation; but it is impossible, as a general rule, to give an anæsthetic in a case where one requires very carefully to study the action of poison on the various functions. There is undoubtedly a disturbing influence brought about by the action of anæsthetics.

5362. With regard to those latter experiments, those upon poison, are they generally very protracted?—They may be so.

5363. But not in the majority of cases, I suppose?—Not in the majority; and a large number of these experiments are not at all necessarily connected with the infliction of pain.

5364. Now there is a third class of experiments, that consisting of the inoculation of a disease for the purpose of watching the progress of that disease in the animal. I suppose there the inoculation may either be treated, as like vaccinating a child, too small a thing to be regarded as painful at all, or, if it amounts to anything like serious pain, you can perform it under anæsthetics?—Clearly; the mere inoculation in such experiments is but a very slight matter.

5365. The only pain that is inflicted upon the

Mr. A. Gamgee, M.D.

4 Nov. 1875.

animal then is the consequent pain of suffering from the malady?—Yes.

5366. And of that we cannot, I suppose, ask you for any other definition than that it must be the inconvenience and discomfort of the malady, whatever that may be?—Yes.

5367. In those cases you do not permit the malady to run its whole course. The object of the experiments is to test it at various stages of its course, is it not?—Clearly; although one can well understand that where the result of the malady might be sought for, the experiment would be pursued to its end.

5368. That would be a rare case, would it not?—Decidedly a rare case.

5369. The shorter period would be generally the period at which the animal would be destroyed for the purpose of anatomy?—Generally.

5370. Do you at all suppose that it is the practice of any of your students to perform experiments upon animals in their own lodgings or in secret?—I would wish to express myself unhesitatingly on that matter. I believe it is not at all the custom. I believe that at the present time vivisection is only performed by very few persons in the kingdom; and, except in very rare instances, in the physiological laboratories attached to, unfortunately, very few public institutions.

5371. Then I may take it that you consider it to be performed by the most competent persons, with the most definite object, and in the most humane manner?—I do.

5372. (*Lord Winmarleigh.*) How long have you held your present office?—I have been professor of physiology in Owens College since the month of September 1873.

5373. Are there any rules connected with the study of physiology there which could restrain experiments by others than those especially devoted to that subject?—In virtue of my position I have the entire direction of the physiological laboratory of Owens College, and have absolute authority over all persons working in that laboratory; and I have certainly never permitted anyone to perform any experiments, except such as have been sanctioned and generally superintended by myself. No medical student, as such, has ever performed a physiological experiment. All the experiments for purposes of tuition are performed by myself, as a general rule after an introductory lecture in which I have stated what has been ascertained on the question, and the experiment has been performed for the purpose of illustrating my statements, the animal being in a state of anæsthesia and afterwards being destroyed. No student has ever, except for the purposes of research, (not as a medical student proper,) performed an experiment.

5374. Then you do not permit under any circumstances a student to operate even under your own direction in the laboratory?—Not unless the student is so competent that I should think him a person well fitted to perform an original investigation. Under these circumstances students have performed experiments, and I shall be most happy to inform the Commission exactly as to the details, the students whom I have entrusted with this power, and the results of their experiments.

5375. But any such experiments of that kind, conducted under your superintendence, would always be performed under anæsthetics and without cruelty?—Except in cases where the physiological action of a drug, or some other important fact is to be investigated, which makes the employment of anæsthetics impossible. Now it appears to me undoubted that such cases will arise in the future as they have arisen in the past. A highly competent student of Owens College who holds a physiological scholarship attached to my chair, Mr. John Priestley, has made an elaborate investigation into the compounds of a very rare metal, vanadium. This research was entirely planned by myself, and the experiments were first of all performed several times by myself; and I believe that every good teacher of physiology, before setting a student to any investigation, always takes that precaution. Mr. Priestley then with great care and humanity repeated the experiments which I considered it desirable should be performed, in order that the action of this poison should be known.

5376. Do you think it would be prejudicial to the scientific object of your department to introduce any regulations restricting experiments to persons properly qualified?—I am not prepared to answer that question. Perhaps the Commission will allow me to say this, that in reference to physiological laboratories I think there is no need for any legislation. I am sure from my pretty extensive experience that great humanity characterizes the practice of all who have the superintendence of such laboratories. I am, however, on principle, quite prepared to say that it might be advisable to restrain the possible performance of vivisection by persons not competent, and who are not working under the eye of a responsible person.

5377. Now could you suggest to the Commission any mode which would carry out the object which you have just suggested with the least possible detriment to the prosecution of science?—The question takes me rather aback, as I have not thought of it. As a rule I think that physiological science will not be advanced by private researches carried on by individuals with their own private resources. I would explain that statement; most physiological experiments are now performed with instruments of great delicacy, which require for their use long training, the training which as a rule can only be obtained in a physiological laboratory and under the guidance of an expert physiologist; few private individuals, except those who have really undergone this long training, could I am sure advance the science by private research.

5378. Could you draw any line, or could you suggest to this Commission any line which could be drawn, below which experiments should not be made? In other words, could you suggest any qualification on the part of a student or other person without which no experiment should be made?—It is extremely difficult to draw such a line. Speaking of students, I would say unhesitatingly that they should be entirely disqualified from performing any independent experiment. I have no hesitation in giving an opinion on that matter. On the other hand, there are a few (I am just now thinking of one) highly qualified physiologists not connected with phyiological laboratories, and possessed of such great skill that it would be a great hardship to rob them of the privilege of contributing to the branch of science which they have already adorned.

5379. (*Mr. Hutton.*) Would you mind mentioning the name?—The name which first suggests itself is that of Dr. Fraser, the Medical Officer of Health for Mid-Cheshire, a gentleman who has made researches on the action of many drugs.

5380. He however is a well-educated medical man?—Yes, a man of the highest culture.

5381. (*Lord Winmarleigh.*) Do you think that a system of licenses could be introduced which would not be prejudicial to science?—I can quite conceive of it, if no vexatious interference were exercised. If no vexatious spirit guided those who gave these licenses, I think they might be given with great advantage.

5382. But those licenses must be given with certain restrictions, of course; and could you suggest to us what those restrictions should be?—It is very difficult for me to give a decided answer and commit myself, as it were, to a decided opinion. I should be most happy at another time if the Commission will give me the opportunity, to express my view on the matter. I simply object to answer because I should not like to express a rash, and, it may be, an unwise opinion to the Commission.

5383. But you do think that a license might be given for experiments upon living animals which might protect the practice from abuse?—I believe so. I wish however very decidedly to express my conviction to the Commission that vivisection in England has not been practised so as to lead to any abuses. In fact, as I believe that it is very essential for the teaching of physiology and for the pursuit of physiological investigations, and as I believe that physiological investigations are of very great use to the whole human race, I think that vivisection has been practised almost too little.

5384. Are your lectures at Owens College attended by a numerous body of students?—My lectures to junior students are attended this session by 40 students. Those to second-year students by 42 students, I think. So that our medical school is now one of the most considerable in the country,—the largest provincial medical school.

5385. We all know that Owens College is increasing day by day, and most probably will become even more celebrated than it is at the present moment?—I may say that we are making great efforts in Owens College to encourage qualified persons to engage in physiological research; and for that purpose we have provided a laboratory, and we have a physiological scholarship which was endowed by Mr. Platt, for the purpose of encouraging original physiological investigation; it is a condition required of the holder of that scholarship that he shall have passed an examination in physiology and comparative anatomy, and it may be in some other subjects, and that he shall have carried out an original investigation in physiology. As yet we have only elected one Platt physiological scholar, Mr. John Priestley; and the investigation which he performed, which I just now referred to, is one on vanadium, which is about to be read before the Royal Society.

5386. (*Sir J. B. Karslake.*) I think I infer from what you have said that in your judgment it is essential for the proper tuition of the students under your care that you should exhibit from time to time experiments on living animals?—Certainly.

5387. In your belief could they follow or appreciate your teaching efficiently without having those experiments performed?—I am convinced that they could not.

5388. You have given the name of one gentleman who as a student has engaged in physiological researches under your supervision in your college, Mr. Priestley?—Yes.

5389. All his experiments, I understand, were first of all suggested and practised by yourself?—Yes.

5390. And afterwards he again went through the experiments with a view to qualify himself for this scholarship, is that so?—I am sorry that I should have conveyed such a very erroneous impression to the Commission, and if you will allow me I will correct that impression. In carrying out any investigation in any branch of science it is absolutely essential that observations should be numerous. That is really true of observations in any department of physical science; no single observation, except under the most rare circumstances, is trusted by competent scientific men who exercise due caution. Now physiological experiments are more liable to fallacies than any other experiments; there are so many circumstances which belong to the particular animal which is being experimented on which may lead to a fallacy in judgment, that it is most essential that many observations should be made. In carrying out this research I followed the plan which I believe is followed by all the conscientious physiologists of Europe in the directing of investigations. I selected in the first place a man whom I considered qualified by his previous training to undertake such a research. I caused him to make the previous dissections required for the intelligent performance of the experiments, and I then showed him the way of doing a particular experiment. For example, in taking up a particular kind of investigation, after I had thoroughly instructed him he repeated that experiment, or that kind of experiment, not by any means to *qualify for the scholarship*, but in order to acquire for science the facts which I wished acquired. These facts could not have been acquired by a single experiment, often not by five or six, sometimes not by 10 or 12 experiments. I wish very distinctly that it should be understood that in no case would I be guilty of such conduct as to have an investigation performed *in order that* a person might qualify for the scholarship. If the conditions of the scholarship were such as to involve that risk, I should at once go to the founder and ask him to consent to a modification of the conditions under which the scholarship was given.

5391. Might I ask you this: Did not Mr. Priestley perform experiments, with a view to ascertaining results, which had not been performed by yourself?—Yes, clearly. I only indicated the method to be pursued; I could not say the result that would follow.

5392. So that he, in your laboratory, and under your supervision, did perform experiments and make observations which you yourself had not performed or made?—There is a certain amount of truth in that way of putting it, but it is not entirely correct. I had made the experiments, and, in fact, in a few cases were the experiment was one of great complexity I performed it every time. There was one set of experiments which I thought so difficult that it would require practising upon animals for a considerable time to give Mr. Priestley the due facility, and therefore I performed that part of the research myself, he helping me. I was the operator. I do not say that I was the observer. Mr. Priestley was perhaps more the observer than I was.

5393. Mr. Priestley's name has been introduced by you as that of a gentleman who has been in one of your classes of students in Owens College, and whom you considered a person quite efficient to be intrusted with physiological research and making experiments, at all events under your care, is that so?—Certainly.

5394. Now with regard to what you said about licensing, and the performance generally speaking of these experiments in physiological laboratories, what would be the objection at the present time to Mr. Priestley making independent researches in his own private laboratory?—I think that those who read Mr. Priestley's paper, which is yet unpublished, will say after reading it that he is exactly one of those persons who might very safely be entrusted with a license.

5395. And I suppose you would hope that other persons like Mr. Priestley will be turned out of Owens College?—Yes, although I confess that I am not sanguine that we shall have a great number of young men who will, as Mr. Priestley has done, devote themselves for years to the pursuit of physiology.

5396. Still the thing is possible?—Yes, it is possible.

5396*a*. Have you at all considered the question, supposing a license were given, who is to suggest the name of the person who should be licensed, who is to say on what terms he is to be licensed, whether he is to be licensed to carry on experiments in any particular place, and any other questions which are involved in the licensing question?—That forms rather a part of a previous question which I declined to answer. If I had had a very short time to think over it I might have given a consistent answer. I should scarcely like to commit myself now on so important a matter.

5397. (*Mr. Hutton.*) Did I not gather that you do not regard it as necessary to exhibit the action of painful poisons in your ordinary class as a demonstrational experiment?—Certainly not at all important. I have never done such a thing.

5398. You do not exhibit for instance the action of strychnine on an animal?—I have never done so.

5399. And you do not think it necessary to do so?—I would not like to condemn another physiologist who thought it advisable.

5400. Still you do not in your own opinion regard it as advisable?—I do not in my own opinion; still if I were giving a special course of lectures on the action of poisons to young medical men, I would not think it wrong to perform such experiments. I would think that the end to be gained justified them.

5401. Do you find it necessary to perform experi-

Mr. A. Gamgee, M.D.

4 Nov. 1875.

ments on arterial pressure in your own class ?—Yes, often.

5402. Are they all under chloroform ?—All under chloroform or chloral, or the combined influence of chloroform and morphia.

5403. You do not regard curari as an anæsthetic? —I have never used curari in a class experiment. Certainly in the early stages of its action curari is not an anæsthetic. I think that undoubted ; there are a number of facts known to me which lead me to say so. There are other facts, however, which lead one to think it probable that as the result of the administration of large doses after a certain stage is passed sensation is affected.

5404. Has Mr. Priestley got a medical degree ?—He has not yet got a medical degree.

5405. Would you think it very inconvenient if such a qualification as this should be required, that any man operating for himself, and not operating under the inspection of a physiologist like yourself, should have a medical degree, should have passed through a physiological laboratory, and should have got the certificate of the physiological lecturer that he was qualified to perform experiments and was likely to perform them with all possible humanity ?—I think it would be most inconvenient to require the possession of a medical degree, because physiology is now commencing to be studied as a special branch of science for its own sake. For example, in Cambridge, many are, I believe, pursuing its study for its own sake; and I have no doubt that the study will be in a little time generally pursued. In Mr. Priestley's case, I think it would be a very great hardship if a medical degree were required from him ; because he has qualified himself by devoting himself for two years to the study of physiology. In qualifying for this Platt scholarship he had to subject himself to a most stringent examination in physiology and comparative anatomy; and I should consider that if such a restiction were imposed upon such a man it would be a very vexatious one.

5406. (*Lord Winmarleigh.*) Have any experiments been made on the human frame of the effects of curari ? —Yes.

5407. What was the nature of them ?—I performed some experiments myself on the action of curari. It had been stated by a German physician, whose name I do not remember just now, that curari in very small doses was a serviceable remedy in the treatment of some nervous affections, more especially of epilepsy; and being connected with the Children's Hospital at Manchester, I commenced some very careful experiments with this drug in the case of children who were almost hopelessly epileptic, carrying on the administration of the drug with very great care, first giving very small doses, and then increasing them very gradually. At first no result whatever followed; and as the disease was not in the least affected, it appeared desirable to produce some physiological effect to show that curari was being given in such doses as to affect the system, and in these cases some very interesting phenomena were produced. Naturally I only induced the very earliest effects of curari in the human subject, knowing by my experience on animals that to give the poison in excessive doses would have been to imperil the lives of my patients; but in two cases where a certain dose had previously produced no effect, so that I fancied I was within perfectly safe limits, a repetition of the dose produced some slight and very transient phenomena of paralysis. One little girl, for example, who was a peculiarly stolid and unexcitable child became obviously frightened; a slight paralysis of the muscles of expression occurred; she complained that she could not raise her arms, and on rising to walk she fell. I was an eye-witness of the symptoms produced. We removed her to a bed ; the circulation went on quite satisfactorily, the respiration becoming almost anxiously shallow. The symptoms very rapidly passed off. Now in this little patient I was able to determine very decidedly that sensibility was not at all impaired ; although there was a certain amount of paralysis of motion produced by the curari there was no affection of the sensory nerves. And this observation I was able to confirm by others upon another little patient. After the performance of these two experiments it appeared to me that I had evidence, firstly, that the poison did not in any way control the disease, and secondly that even in small doses it was so dangerous as to render it inexpedient to pursue the observations. I think it right to add that the observations were carried on with extreme care, and with every appliance ready in the event of respiration becoming arrested.

5408. Were any of those cases attended with pain at all ?—No.

5409. You have not made any experiment of the sort in a case where the patient was suffering pain, and could tell you the effect of the curari afterwards ? —No. I believe very few experiments have been performed in which the administration of the drug was pushed as far as in the cases to which I have been referring. I had the opportunity of being for some time this summer with the most distinguished French physiologist, Professor Claude Bernard, to whom we owe the first accurate investigation of the action of curari, and he was extremely interested when I described to him my observations, and he thought them almost singular from the extent to which the poison had been pushed. Indeed, I promised to send him the observations, so that he might publish them in any future paper which he writes on that subject.

5410. M. Claude Bernard did not tell you of any experiments which he had himself made with curari on the human frame ?—No; he had distinctly not performed any. I believe he told me that experiments had been performed with it at La Salpêtrière in Paris, but that the doses had not been pushed to the same extent as in the cases which I described.

5411. It is your experience that curari does not diminish pain ; is that so ?—I would not go so far as that. There are some facts which would almost show that at a later stage the spinal cord and the brain are affected by it. It is, however, conceivable, I should say, that an anæsthetic action is not an essential result of the introduction of curari. I think it is probable that curari may paralyse the motion of the body without affecting the sensory nerves or the nerve centres of the body.

5412. (*Chairman.*) But with reference to the more immediate subject of our inquiry, you are of opinion that in inflicting operations in themselves very painful upon living animals, curari ought not to be trusted as taking away sensibility to pain ?—I should think not. I would add this: I do not believe that physiologists use it for that purpose. It is used in order to eliminate a series of fallacies which obtrude themselves in physiological experiments; and it is conceivable that curari might be used (in fact I have no doubt it might be), if required, even in connection with anæsthetics. Many of the experiments in which curari is administered are not very painful experiments. It is not given to prevent the cries or the movements of the animal, but as I have said to eliminate certain disturbing influences.

5413. But if the object was to use an anæsthetic to relieve the animal from pain, it would not be right to trust to the operation of this particular drug ?—It is my individual opinion that it would not.

5414. (*Mr. Hutton.*) May I ask whether your answer as to the absolute anæsthesia of the animals experimented upon in your lectures applies to frogs also, or only to the higher animals ?—It applies to all. In experiments on frogs, however, I have very rarely administered or used anæsthetics, but I shall explain to the Commission why. These experiments have been performed when the animals have not been capable of suffering. In the immense majority of cases experiments on frogs may be performed after destruction of the nerve centres, after decapitation and, if need be, after destruction of the spinal cord. Now it is obvious that decapitation or destruction of the

Mr. A. Gamgee, M.D.

4 Nov. 1875.

nerve centres may be performed with such rapidity as to cause very little pain indeed. When decapitation is practised, I always crush the brain, and I am in the habit of pointing out to the students that I take that precaution for certain obvious reasons. It might be that in a cold-blooded animal the structures still in connexion with the brain might retain their sensibility even after a great hæmorrhage. There are innumerable facts which make it almost certain that if a person were decapitated the head would not feel. Now it is conceivable that things may be different in cold-blooded animals. Their tissues are capable of living for a longer time when deprived of blood; and therefore I have always been in the habit, after decapitating a frog, of at once crushing the head.

5415. (*Lord Winmarleigh.*) Are there many experiments on frogs in which you cannot relieve them from pain in the way which you have just described?—I think there are very few. I should like to point out this fact, which is known to all physiologists, that in cold-blooded animals the life of the tissues persists for a long time after the life of the body has ceased; death of the tissues in no way corresponding in point of time with the death of the whole body. But anæsthetics might be used; for example, placing the frogs in a watery solution of chloroform is an admirable method of rendering them very rapidly insensible to pain; they remain insensible for a long time if placed in water which contains very little chloroform.

5416. (*Mr. Hutton.*) Have you studied much abroad?—Not for a long time; but to a certain extent both in the University of Leipsic, in the University of Heidelberg and in Paris.

5417. Has it occurred to you to know much of the foreign physiologists, I mean as distinguished from medical men?—Yes, I know several of them pretty intimately.

5418. Do you not think that a good many of them perform experiments which the English pysiologists would mostly regard as needless and even wanton?—I confess to you I do not believe it. I do not know one such. I will say all I know on the subject. If by "wanton" you mean experiments which are not absolutely required for the purpose of scientific discovery, then, perhaps, the expression is true. For example, I was referring a short while ago to a late visit to Paris, and to my interviews with Professor Claude Bernard. On that occasion Professor Claude Bernard did perform certain experiments simply for my instruction; but these experiments were by no means wanton experiments. I was very anxious to know how to perform certain experiments which he had been the first to devise, and he performed these; and amongst others he was particularly anxious to show me the effects of certain anæsthetics, or certain modes of administering anæsthetics, which made it possible to perform almost any experiment painlessly on animals. I have referred to Professor Claude Bernard; I might refer to Professor Ludwig of Leipsic, as a man who, I am certain, is as cautious in the performance of any experiment on a living animal as any English physiologist that ever lived, and who yet has been the teacher of nearly all the physiologists of Europe, and has indoctrinated nearly the whole of them in the methods of physiological inquiry. I think in the several laboratories of Europe, with which I am acquainted, anæsthetics are made use of, except in cases where their use would distinctly interfere with the investigation.

5419. (*Sir J. B. Karslake.*) I infer from what you said just now that Claude Bernard seems to have paid particular attention to anæsthetics and the proper mode of administering them?—He has. He has very lately published a book on the physiological action of anæsthetics, a book of great interest and of great use to persons who have to perform experiments on living animals, so admirable are the directions for properly anæsthetising animals.

5420. (*Chairman.*) You hope to see the day when laboratories like that of Owens College will be multiplied in this country?—I do.

5421. And you regard them as affording means of making physiological investigations which cannot be afforded elsewhere?—Undoubtedly.

5422. Therefore where such investigations are performed by private persons and in private places, you regard them as exceptional cases?—Yes.

5423. And you regard those exceptional cases as likely not to increase but to diminish in proportion as what you wish to see increase?—Yes, very decidedly.

5424. And although you have not considered the detail of the subject, yet having such an increase of great schools in view you see no objection but quite the reverse to the establishment of some reasonable regulations for such institutions?—I see no objection to it.

5425. I need scarcely ask you whether if some regulation were proposed on the subject which should, without limiting the progress of science and the efforts of competent scientific people, restrain the performance of operations upon living animals by incompetent persons, for no definite object and without proper precautions, there would be any sentiment on your part that you had been affronted by such a regulation?—Not at all.

5426. Nor would you at all sympathise with anybody else who thought it would be an affront to the promoters of the advance of science in this country?—Certainly not.

5427. All therefore would depend upon the reasonableness of the measures and the question of whether they really tended to interfere with the progress of science?—Clearly.

The witness withdrew.

Mr. GOERGE JAMES ALLMAN, M.D., called in and examined.

Mr. G. J. Allman, M.D.

5428. (*Chairman.*) Are you Emeritus Professor of Natural History in the University of Edinburgh?—Yes.

5429. You have paid, I think, a great deal of attention to the subject which has been referred to us?—A great deal in a general way, but not specially; and I should be rather sorry, considering that I have not applied myself specially to physiological research, if the Commission should be disposed to place more value on my evidence than I do myself.

5430. Is it your opinion that the practice of trying experiments upon living animals should be altogether put an end to?—No, certainly not.

5431. You consider that those experiments are necessary for the progress of science?—I do.

5432. Do you think that it is possible to carry on those experiments in such a manner as to advance science and its application to the alleviation of suffering in the human family, while at the same time taking measures to exclude any abuse of the system?—I think it is quite possible.

5433. Now have you thought at all of what limits you would be prepared to recommend?—I should certainly recommend that no experiments on living animals should be performed without throwing the animal first into a state of insensibility by some means or another, except in cases where the state of insensibility might interfere with the value of the results.

5434. Is it your opinion that in the majority of experiments upon living animals for the purpose of observing the healthy process it is possible to perform those experiments while the animal is under complete anæsthesia?—I think it is quite possible.

5435. We have been told that in the majority of other cases, though the whole of the proceedings cannot be conducted under anæsthetics, the most painful part of them can be, is that your opinion?—Unless

Mr. G. J. Allman, M.D.

4 Nov. 1875.

an actual case was put before me I should hardly be prepared to give an answer to that question.

5436. We have been told that there are important experiments tried to test particular modes, for instance, the tying arteries, and that while the original operation is painful the process of recovery in the human person is not very painful, and it is contended that it is quite legitimate to operate upon an animal under chloroform and then to observe the process of recovery, without of course its being possible to continue the anæsthetic operation ?—I think it is quite possible to perform the operation under the influence of chloroform.

5437. And would you say that a case like that was a case which might be permitted ?—Yes, but you could not continue the animal under the influence of chloroform so as to observe the subsequent progress of the case.

5438. That I assume. The question I put to you is whether such an experiment falls within your notion of being a right and proper experiment ?—Yes.

5439. Have you considered the bill which was laid before the House of Commons last session by Dr. Lyon Playfair ?—Yes, I have read it.

5440. And do you consider that in general it is a suitable bill ;—I do ; upon the whole I think the bill a good one. I think there are some points in which it might be improved, but I think it very much better than the bill brought in by Lord Hartismere.

5441. Do you attach importance to the keeping of a register of all the proceedings in regard to living animals ?—I do.

5442. In which everything that takes place should be recorded with accuracy?—All cases at least which are performed without the application of anæsthetics.

5443. Do you think that for the purpose of education it is at all necessary to exhibit experiments which are not performed under anæsthetics ?—Certainly not ; I think there is no necessity for such.

5444. Where a doctrine is already established, and the experiment, if performed, must necessarily give considerable pain, do you think it is legitimate to repeat it ? —It depends there very much upon what we regard as a doctrine being absolutely established. There are many cases I should say in which the evidence brought forward for the truth of certain doctrines stated may not bring conviction to a physiologist's mind, and I think under such circumstances he would be justified in repeating the experiment.

5445. It depends then upon the fact of whether the doctrine is firmly established or not ?—Yes.

5446. But where a doctrine is firmly established, and the experiment is necessarily very painful, take for instance an experiment upon the roots of the nerves, to repeat that which Sir Charles Bell firmly established, do you consider that legitimate ?—I do not.

5447. Are there any other observations which you desire to offer to the Commission ?—I think not.

5448. (*Sir J. B. Karslake.*) With regard to one answer that you gave, let me put this question : You yourself have never used experiments upon live animals for exhibition to a class ?—Not for exhibition to a class. In some investigations of my own I have tried experiments upon frogs, but nothing more.

5449. With reference to the actions of poisons we have been told that in certain classes the action of strychnia upon an animal has been exhibited, because it is suggested that students cannot obtain accurate knowledge of the symptoms attending poison by strychnia without seeing a case. Would you say that persons expressing that opinion are incorrect ?—I should be inclined to think so. I should not like, however, to speak very positively, as it is not a subject on which I have had any personal experience ; but I should think that descriptions of the tetanic results of strychnia are so plain and intelligible that it does not need the thing to be actually exhibited to the students in order to give them a correct idea of it.

5450. That would be your opinion ?—It would be my opinion.

5451. But you say that you do not express any very strong opinion upon it, not having had any experience in exhibiting to a class yourself ?—No ; I merely give that as my opinion, for what it is worth.

5452. (*Mr. Hutton.*) You seem to say that the register of vivisections should be limited to experiments made without anæsthetics. Now do you not think that there is enough doubt about the completeness of the anæsthesia to make it desirable that the register should include all experiments on living animals, with a specification whether they were under anæsthesia or not?—Of course that is a practical point for consideration. If we were sure of the experiments being performed under anæsthesia, then I should say there was no necessity for recording them.

5453. But one cannot be sure ; it is so easy to give anæsthetics for the first few minutes and to let the effect of the anæsthetic pass off before the pain passes off ?—If the effect of the anæsthetic passes off before the pain passes off, I think the animal should be destroyed, or, if possible, thrown under a state of anæsthesia again immediately.

5454. Do not you think, therefore, that it would be better to include in the register all experiments, whether under anæsthesia or not ?—It would probably be the simplest way after all.

5455. And as to the killing of animals immediately after the experiment, I suppose you would enforce that in any case where they had been seriously injured ?—I would.

5456. Unless it were absolutely necessary for the result of the experiment to watch the progress in the living animal ?—Yes, with that exception, provided the injury was likely to produce prolonged pain to the animal.

5457. (*Chairman.*) Have you anything further you wish to say ?—No, I have not ; except that I should almost feel inclined to suggest the appointment of a Board of Control. I think that if physiological experiments are tried in licensed places, inspection should be allowed, and that a board should be appointed with a power of visiting and seeing that there was no abuse. I should think that all difficulty would be got over by such a plan as that.

The witness withdrew.

Adjourned to Saturday next, at 12 o'clock.

Saturday, November 6th, 1875.

PRESENT :

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

Sir WILLIAM WITHEY GULL, Bart., M.D., called in and examined.

5458. (*Chairman.*) Were you lately teacher of physiology at Guy's Hospital, and also teacher of medicine there ?—Yes.

5459. And are you now consulting physician there? —Yes.

5460. And were formerly Fullerian professor of physiology at the Royal Institution ?—Yes.

5461. I need hardly ask you if you are a physician in extensive practice in London ?—Yes, I have seen a good deal of disease.

5462. You have paid, I believe, a great deal of attention to the subject which has been referred to us? —I believe I have unusual attention.

5463. Would you have the kindness to state your views upon it ?—First I should like to say that I have inquired whence the movement sprang—what, so far as I could make out, were the facts which have excited public attention, and so far as I can learn I know of no facts in England that would have excited such attention, but so far as I can learn (but this I shall only say as hearsay) there have been reports of experiments on animals abroad which have excited a sentiment against the practice of vivisection. But I should like very much to be guarded in that expression ; because the persons who have performed those experiments are not here to answer for themselves ; and, besides, I believe it to be so contrary to the spirit of scientific inquiry to give any unnecessary pain, or in any way to give licence to a cruel spirit or to an indifferent spirit even, that I should be very slow without exact evidence to believe those reports. I should also be more slow to believe them, because I know that those who have reported them are not people in whom I should have confidence. I believe that the public feeling has been excited by reading a recital of experiments asserted to have been made, which, if made at all, were not made in this country, but which the public have interpreted as having occurred here.

5464. Are you of opinion that experiments upon living animals are necessary for the progress of surgical and medical science ?—I am certainly so.

5465. Are you of opinion that the tone of sentiment in the minds of those who practise such experiments in this country is a sentiment of indifference or a sentiment of humanity ?—I should say essentially a sentiment of humanity.

5466. Is it the case that the great majority of such experiments may be performed when the animal is entirely under the influence of anæsthetics ?—Certainly, and they are so.

5467. That of the remainder a majority may be performed in such a way that the most painful part is done under the influence of anæsthetics ?—Quite so. I think there are but few experiments performed on living creatures where sensation is not first removed ; I think the removal of sensation is necessary to the success of an experiment very often or indeed most often.

5468. Is it your opinion that the students as well as the professors are impressed with a sentiment of humanity, and would be intolerant of the infliction of pain which they believed to be unnecessary ?—I believe that in a medical school anything like cruelty or indifference to suffering would be scouted by the public opinion of the students. I have never seen any indifference.

5469. Is it your opinion that of that small remaining portion of experiments, those where anæsthesia cannot be induced without destroying the success of the experiment, there are many in which anything like protracted agony need be, or is, inflicted ?—I personally know of none where suffering forms any necessary part. In all the experiments on living creatures, so far as the mere suffering goes it complicates and perverts the results.

5470. Take for instance experiments where sensation is in question, those I presume must necessarily be painful ?—Yes, there are very few of such ; there are hardly any that I could at the moment recall. Of course science must have its own progress and I cannot forecast what line it may take ; but there are very few experiments on nerves of sensation.

5471. Then we may assume that if experiments on the nerves of sensation were repeated for the mere purpose of examining into facts which have already been established, like those established by Sir Charles Bell, you think that such repetition would excite the reprobation of the teacher and the pupils, as well as of the public in this country ?—I quite think it would.

5472. Have you directed your attention to the question of whether any legislative measures may be introduced upon the subject without interfering with the progress of physiological science, and if any such measures can be introduced whether there is any objection to them ?—If legislation were calculated to hamper either scientific enquiry or the pursuit of science I should think it most deplorable.

5473. But if it were clear of that objection then you would see no difficulty about it, would you ?—Even then I should see a moral and very serious objection. It would imply that the scientific men of this country and the students of science required legislation, which I deny.

5474. But supposing that the object of the legislation were not to impede the progress of science in the hands of competent and scientific and studious persons, but to prevent vivisection being attempted by incompetent and uneducated and unscientific people, what would be your opinion of such legislation ?—Then I should think it superfluous, because I know no such people who do it ; so that I should be on the horns of a dilemma.

5475. But if it were established to your satisfaction that such things were done, would you then see an objection to legislation which should repress the practice in those particular cases ?—I think the particular cases in which it would need repression would be cases of cruelty to animals which would be dealt with by the common law. I have thought a good deal on the question how far any possible legislation would not throw a shadow upon the fair prospects of science, and I feel this, that as all legislation must hamper and must hinder, which all legislation is intended for, because it is intended to restrict, such restriction where it was necessary might fairly, and might I am sure, as regards public morals and public decency, be left to the high sense of the teachers or the students of science, and the public ; that whatever legislation could do would be repressive, and would be a distinct assumption that there was a public scandal in a certain way, limited more or less, but still a public scandal calling for legislation ; because legislation could only be called for if there were such a scandal, and the prevalence of it were sufficient for legis-

Sir W. W. Gull, Bart., M.D.

6 Nov. 1875.

lation. Now I must say that with my personal knowledge and long experience, both in public and private life, from living at a hospital for fifteen years, being acquainted with one of the greatest schools in this country, having been occupied with physiology for fourteen years of my life, and having a full acquaintance with medical men and medical students, and with the difficulties that science has to contend against, and looking at the whole subject, I should regard any legislation as repressive or hampering, or as casting a shadow where it is not deserved. There may be isolated cases of abuse, but I doubt even that; I doubt whether anybody but a madman would seek to inflict pain for the pleasure of it; I do not know of such cases. I should regard it as an evil day for this country if the Parliament of England should think itself called upon to interfere.

5476. You would think it implied that there were abuses in the country which you did not believe to exist?—Yes, that is what I should think. I should regard it as throwing a shadow, as I have said, upon our fair fame, which fair fame should not, I think, receive such a blot. Moreover, I think there is such a tendency to ignorance; there is such a tendency to be satisfied with the knowledge we now have; there is such a desire to be governed by what I should call weak sentiment—I do not speak unfairly or unkindly, but there is such a desire that I am sure that even the mildest legislation would do harm to the progress of science; not to the progress of science in a higher sense, because I think it would not hinder the scientific men of this country from pursuing their inquiries; but I think it would prevent the spread of scientific knowledge amongst students who are already too glad to get their knowledge out of books.

5477. By that do you mean that students ought to be encouraged to perform these experiments?—No, but I think they ought to see them.

5478. But supposing every opportunity were afforded for students to see the experiments, do you then think that to repress any tendency to experiment either in an indifferent and reckless manner, or to conduct experiments through the means of uninstructed and incompetent people, would be a slight upon those who were highly competent and well instructed, and with whom the law did not at all interfere?—It would assume that there were such people, which I doubt.

5479. That is the foundation of your objection?—That is the objection that I have.

5480. If it were shown that there was any sufficient cause for it would you then object to legislation?—Then I think you must legislate; then science is gone in this country, and public morals. I really think that. If there is such an area of indifferent, ignorant, and cruel experiments on living animals as would warrant legislation, then I seriously think that we are in a state of great decadence; but, as I believe that does not exist, therefore it is really for the fair fame of our country that I am pleading. I think it would be a grievous thing that we should be put into a false position in this matter.

5481. In many countries there do not exist, I believe, laws for the prevention of ordinary cruelty to animals. In England there is such a law. Do you think that the character of England for humanity has suffered in comparison with those other countries by the enactment and continuance of that law?—In the first place I do not know of the law; I only know of the action of the Society for the Prevention of Cruelty to Animals; and if I were asked I should say that that Society has not done great service, or no more than would have resulted without it.

5482. I do not understand you to think that England has suffered in reputation from the existence of that law?—No, I think not. I ought to add, however, that those laws would be made for the ignorant, and not for the best people in the country. I mean to say that there might be very different legislation for the ignorant and the indifferent, as compared with the pursuers of science and the students of science.

5483. Then you assume that the question is whether the law shall operate upon that highly elevated and excellent portion of the community who really would act humanely without any law?—I think so.

5484. But if the reason in this case should be the usual reason for a repressive law, that it shall operate upon a totally different class of persons, what would you say?—Then I should see less objection. I will put it thus: I can understand that a father would have an Index Expurgatorius for his children, but I should think it a very serious thing if he had it through the whole of their life. That is how I should think of it.

5485. Then in short it is that you feel a difficulty lest it should be understood that the highly estimable and highly instructed people, with whom you have been principally acquainted in connexion with this question are the persons pointed at by the Statute?—I should feel this difficulty.

5486. But if that were perfectly clear your objection would comparatively vanish, would it not?—Well, not altogether; because I should be troubled with the assumption that there was still a prevalence of scandal, which I doubt. But of course if the Commission or Parliament is satisfied that there is such improper practice they must legislate; I however doubt the existence of it.

5487. I suppose it consists with your knowledge and experience that the disposition to study physiological science by the use of experiments upon living animals has by no means attained its maximum in this country, but that on the contrary it is now making rapid progress?—Even that I could not say. I do not think that is so. What I think is making progress, and what I hope will spread, is that men should acquaint themselves more with the actual facts of life as far as is becoming. I do not know that scientific inquiry into living phenomena upon animals by the highest teachers of our race is more going on now than it was in the time of Harvey; I should doubt it. I may tell the Commission (but most of the members of it probably know the facts better than I do) that there was a time when there was a great deal more vivisection than now; for instance, when the circulation of the blood was discovered there was a very curious excitement about vivisection; with regard to the transfusion of blood the whole thing came as a most strange revelation upon the public. Many vivisections were then practised.

I think that the desire of all good teachers to bring their students into relation, as far as it is becoming, with living phenomena is increasing, and I hope it will increase; and I think that accounts for physiological laboratories; but I think that the public should know that that is quite apart from torture or cruelty.

5488. (*Sir J. B. Karslake.*) I think I have already inferred from what you say that you think it essential to the due teaching of students that they should witness these experiments on living animals to some extent?—To some extent, or to any such extent as the state of our knowledge or the state of science may make desirable. I should not like to limit it by saying to what extent, because to-morrow there may be a different idea from to-day; I cannot say what the limit should be.

5489. Now supposing it were to come to your knowledge that there were in this country persons largely engaged in physiological research and pursuits who avowed that they thought they might perform operations on living animals without taking the trouble of administering anæsthetics, except for their own convenience, would that alter your judgment at all as to the expediency of legislation?—Well, it would not. I should say, though I should not agree with such individuals, and though I should think it a thing, so far as I was concerned, to deprecate, if a man who had more knowledge than I have, or more love of science than I may possess, should think it desirable in the high purposes of his mind to perform a given

Sir W. W. Gull, Bart., M.D.

6 Nov. 1875.

experiment, I should certainly not think that the outsiders should have any right to rush upon him and say "You shall not." I am supposing a man who in his high purposes has a distinct experiment which he thinks should be performed in the interests of humanity; and I am supposing that that experiment might imply a great deal of suffering. I should not think it desirable to hinder him, though I might say to him, "Could not that be done differently," or might express my opinion about it, still I should think it my duty to defer to his intentions, believing that he would not, and that no student of science would, as a student of science, do that which was not worthy of him. I will put it thus, and answer the question in another way: Would it be considered right to take an unwilling man and an innocent person, and slaughter him for the public safety? Yes, decidedly; it is done every day in war. You take an unwilling man, and you slaughter him for the public safety. I see no reason in the nature of the thing why an animal should not be slaughtered for the public good, for the teaching of science, if it should so seem fit to a man in whose intention I had confidence. If he were a madman I think he should be brought under the law regarding insanity. But take a man in the pursuit of science—I will take, for instance, Harvey—and I will suppose that another Harvey should come; if he should say, "I see my way to a certain inquiry, and I am going to do it," I think you could not, or, at least, should not hinder him.

5490. I think I did not make myself quite understood. I am supposing a case where a person avowed that he could perform the operation which he desired to perform after having put the animal into a state of anæsthesia, but that he says, "I consider that I am " at perfect liberty, without reference to the animal's " feelings, to perform the operation I desire to per- " form, and which I might perform under the influence " of anæsthetics, without resorting to them at all"? —I think such a man should be blamed, and is open to public censure.

5491. (*Chairman.*) Do not you think he should be repressed?—He may have said something of that sort out of bravado; but as a matter of fact his colleagues would not allow him to act in that manner; they would say, "Do no such a wanton thing as that"; I feel sure of this, if I know humanity at all.

5492. You think that the moral control of his acquaintances ought to be brought to bear upon him?—Certainly; and it would be.

5493. And you would not hesitate, perhaps, to use words which we have heard from a very eminent authority, that indifference to the sufferings of animals is worthy of all detestation and abhorrence?—Certainly; animal suffering is as much to be considered, ceteris paribus, as human suffering. Certainly, an animal should not be wantonly put to suffering.

5494. (*Mr. Huxley.*) I understand that you object to legislative interference with scientific men on the ground that there is no evidence of the existence of any abuses in this country which could justify such interference?—Quite so.

5495. There is another consideration which has been brought before us, and which perhaps has led scientific men to feel more strongly than they otherwise might do upon the question; they have a feeling that there is not only a want of necessity for such legislation, but that if such legislation takes place it will be the worst kind of legislation, unequal legislation, inasmuch as it will propose to inflict restraints, or perhaps pains and penalties upon them for doing certain things, while the other classes of the community, for totally different motives, and for what many will say are far less worthy motives, are doing precisely the same things without any legislative interference. Are you acquainted with the existence of any feeling of that kind?—Yes. I think that is a feeling which does prevail. It is a feeling which has prevailed with one of my friends very strongly in reference to the whole enquiry. But though I should decidedly think it would be very unequal legislation, and though I think that aspect of the case is one which the Commission and Parliament cannot leave out of consideration, I think that what is due to science and the position of science is much above requiring even the aid of what I should call such collateral help. That is the *tu quoque* argument. I agree to it quite, but I think that we can fairly justify our position, and more than justify it, upon its own merits.

5496. It is sometimes asked whether such legislation as that under which cruelty to domestic animals is prevented, and such as the Factory Acts, is not legislation directed to the good of the thing protected. and therefore whether a corresponding legislation in regard to scientific experiments might not be permitted. But then, on the other hand, such an operation we will say as spaying a sow for the sake of making it get fatter a little faster could hardly be said to be a thing done for the good of the animal, and therefore it would need legislative interference just as much as scientific experiments?—Yes.

5497. Not to mention a hundred other instances that occur to one?—Science I think justifies itself. But if I wished to justify it on the lower ground that there are other kinds of vivisection, if you call it so, which are not prevented, one might even go you know very much further. I quite think it would be, as your question suggests, unequal legislation, but I was anxious, if I could, to keep the claims of science apart from those low grounds. I should like it to be understood that I did quite enter into that argument, but that I thought science should be kept from any interference on such grounds.

5498. As regards the increase of demonstrative teaching to which (if I may say so) you justly attach so much importance, may I ask you, as having so much experience as a teacher, whether it is not your opinion that the spread of careful methodical instruction in laboratories is probably more calculated than anything else to diminish any tendency which may exist towards the wanton infliction of pain?—Certainly. I should like to add that ignorance is wanton and cruel, and not knowledge. They are opposed in this.

5499. (*Chairman.*) May I ask you then whether the effect of legislation would not be to act upon ignorance and to leave knowledge untouched?—I should like to know what ignorance, because I do not know the ignorance thus referred to. I can understand that as Parliament is omnipotent it may legislate for anything, but I do not see how it could legislate for a thing which, as far as I know, does not exist; that is what I mean. I may observe that noticing the number of clergy whose names were appended to a public address on this subject, and reflecting what motive (for knowledge it could not have been) could have actuated them, I thought I could see the same spirit as animated the Papal authority in the repression of intellectual progress, and I feel as sure as one can be of an ordinary impression that there is this animus in the matter. We have many motives of which we are unconscious, and I suspect that if we could analyse all the circumstances we should find there is a feeling that we ought not to be enquiring into the profound mysteries, as they are called, of living things.

5500. (*Mr. Huxley.*) From what you have told us there are probably few persons who are more intimately acquainted with the medical students of London than yourself?—Perhaps very few. I lived 15 years in Guy's Hospital with them, and I was occupied in all 30 years with them there.

5501. A statement has been made publicly which I will read to you directly, that the English medical student is attracted by sights of suffering, and is likely to throng exhibitions of animal torture as he would throng no other exhibition. Is that in accordance with your experience of the English medical students? —I should say utterly contrary, and a very serious libel upon medical students.

Sir W. W. Gull, Bart., M.D.

6 Nov. 1875.

5502. The statement to which I refer is contained in a paper called "The moral aspects of Vivisection," written by Frances Power Cobb, and the statement is this: After speaking about students trooping out to see an animal killed, it goes on to say, "The same "keenness of observation, or a memory of their own "youthful insensibility, ought to teach all professors "of physiology that they are indulging a maleficent "tendency which already exists in their pupils dis-"position when they invite mere lads of the Bob "Sawyer type to watch their frightful experiments, "the more frightful, so much alas! the more attrac-"tive." In the whole course of your experience have you ever seen anything which could cause even the remotest justification of that phraseology?—I have not.

5503. (*Mr. Hutton.*) Did I rightly understand you to say that you thought the law against cruelty to animals was made for the ignorant, and not meant for the educated in case they should be cruel?—I cannot say, of course, what was the animus of such legislation, but I should suppose that the Society for the Prevention of Cruelty to Animals was chiefly intended for those who were cruel.

5504. I speak, not of the society, but of the Act with reference to cruelty to animals. Do you not think it should be applied to the educated if they were cruel?—Wherever there is cruelty it should be applied, of course.

5505. I understood you to say that experiments of a painful kind were hardly in any cases desirable in the interests of science; that they were so few, in fact, that the number was insignificant. Was that your meaning?—I said that as regards the teaching of physiology such experiments were few and insignificant.

5506. But I understood you to say that even as regarded physiological inquiry they were so?—I said that as regarded inquiry I could not say that; but whoever should be pursuing an inquiry must be left to his own mind and his high purposes, and to the consideration how far pain was necessary.

5507. But you would not deny that a very large number even of demonstrative experiments may be painful, and that many teachers would regard them as necessary, while others would not?—I could not answer for all teachers; but I should deny that there were painful experiments usually required in scientific demonstration.

5508. What do you say as regards the exhibition, for instance, of the effect of poisons upon animals. They clearly cannot be made always painless?—That depends upon the poison.

5509. Take strychnine for instance?—But we do not poison animals often with strychnine. There may be such instances, but that is not often done.

5510. We have had various lecturers before us saying that they thought it necessary for their classes to see those experiments?—If they were men worthy to occupy the position of teachers, and high minded men, I would not stand in their way, though I might not myself think it necessary to show those experiments. I think there are not many such experiments.

5511. What would you say of the experiments on the nerve system—on the sensory nerves?—If you will tell me what experiments are made on sensory nerves at this moment to demonstrate to students I will answer the question.

5512. Take such experiments as Sir Charles Bell's?—But they are not now repeated before classes.

5513. But we have had evidence that such an experiment might be a legitimate one to show to the ordinary medical student?—If a man is worthy of the position of a teacher, and is open to public opinion, if he should think it desirable to perform any experiment I would not stand in his way. If he erred against public decency he would be open to animadversion. I think it is quite beyond my power or knowledge to say to any teacher of character, "You shall only teach in my way"; it comes back again to the papal authority which says "You shall only read these books." It would be saying in fact that there is to be a physiological Index Expurgatorius.

5514. Supposing it were recommended to try some of these experiments on human beings you would not be in favour of that; there is a papal index as you call it there?—But if that were done the law would repress it, therefore we do not want legislation.

5515. It is not any more a papal index in one case than the other; it is a question of degree, is it not?—Everything is a question of degree. I think you and I are but questions of degree; all is but degree.

5516. I want to get at this—how many of these experiments which are really painful you think desirable? You say that for demonstration very few; but are there not very many performed for the purposes of inquiry?—I may state that I sent to Dr. Pye Smith to ask him to inform me what was going on at Guy's on this matter. I said, "will you inform me what amount "of physiological demonstration goes on at Guy's hos-"pital day by day;" he said, "I am sorry to say, "little or none at all;" I said, "do not the students "come?" he said, I only get about two students out "of 300 to come and see physiological demon-"strations."

5517. But I say, putting aside the question of demonstrations altogether, are there not a very large number of exceedingly painful experiments that have been tried, and are being suggested every day and will be tried for the purposes of investigation?—If you come to the question of investigation that is a thing which I think you must not touch. If the investigators of science are to be legislated for, then science must go to some other country. If we are to lay down how investigators of science are to make their investigations they will have to go elsewhere, that is quite clear, therefore I should not dare to put any limit to investigation.

5518. Now would you hold to that even if it were proved that there are biologists who regard the sufferings of animals as perfectly indifferent, and regard the waste of a few minutes of their own time in administering anæsthetics as of more importance than the agony of the creature?—There are so many "ifs" you see there, but I doubt the fact.

5519. Would you kindly answer the hypothetical question which I have put?—I think that the hypothetical question is so far contrary to the fact that any categorical answer to it assumes the condition that there are such people. I see the logic at once. The object is to assume a hypothetical condition, and to get a definite answer to the hypothetical condition, and then to use the answer as if such things occurred. You first put a hypothetical condition, and you want a categorical answer, and from the categorical answer you would argue towards the hypothetical condition.

5520. Perhaps I may inform you that we have had a witness, of very high scientific character indeed before us, who did assert that view of the case, and who asserted also that he believed that a very large number of scientific investigators on the Continent shared his view; now would that alter your view of the matter?—It would not alter my view of the matter as regards this country; because it does not touch this country as far as I see. It would affect me as it would affect you. I should think that a man who talked so was talking at random, and laying himself open to very serious animadversion.

5521. The point of my question was this, that hitherto we have been acquainted with physiologists who are also medical men, and who take naturally the humane view that medical men do take of all suffering, but that a large school of physiologists are now springing up whose sole interest is the investigation of the phenomena of life, and who might fairly regard, as this gentleman to whom I have referred did regard, the question of suffering as immaterial; what I wished to ascertain was, if there was any chance of that, would you object to putting limits on that kind of inquiry?—I should certainly say that when such a state of things occurs, if it cannot be repressed by the public feeling of those around such

Sir W. W. Gull, Bart., M.D.

6 Nov. 1875.

a man (which I feel sure it would), then it would really be a matter for legislation. You put it hypothetically that there is coming such a race, but I do not know that.

5522. Do you not suppose that the investigation of the phenomena of life, without any association with the alleviation of human suffering, is not unlikely to give rise to a less careful school than that of the scientific medical men ?—Well, I am not so certain of that; because to the scientific inquirer pain is a fact like other things; pain is a fact which he has to consider.

5523. But it does not follow that he wishes to prevent the pain, does it ?—But I do not think it follows that he would not prevent it.

5524. No; but that he may regard it simply as a scientific fact. However, I only wish to put this question: do not you think that there is a danger that where a school of physiologists whose only view is the investigation of the phenomena of life is springing up, there may be much more carelessness of suffering being inflicted than there would be in schools of physiologists who had always been associated with the alleviation of suffering ?—If I were to say I did I should be saying what I do not believe; because that would be saying that I believe Mr. Huxley is more cruel than I am; and I have no reason to think that Mr. Huxley would be more cruel than I should be, although he is a physiologist who has not to do with the cure of disease, and I have.

5525. May I ask you, as you are a great physician, whether you can enumerate to us any considerable number of therapeutic remedies which have been discovered by this process of vivisection; I am of course distinguishing between the diagnosis of disease, upon which everybody knows light has been thrown by it, and therapeutics ?—The cases bristle around us everywhere. Our knowledge of dropsical affections, of pulmonary apoplexy, of engorgement of the liver, and the whole category of such affections is due to Harvey's discovery of the circulation. We knew nothing about them before. Knowing therefore their causes we are able in the same directions to apply the remedies. Then again that same discovery of Harvey's taught us the use of transfusion of the blood in case of hæmorrhage, which is a cure for it. Sir Astley Cooper's experiments on arteries showed the surgeons that they could cure aneurism of the larger vessels, even to the extent of tying the largest vessel in the body; he tied the aorta of a dog, and the dog recovered. Hall, by his experiments on the nervous system, pointed out to us the theory of all the spasmodic affections, and how to apply our treatment by removing the exciting cause; it might be a tooth; it might be a spicula on a bone; it might be the irritation of a wound; all of which is essentially therapeutic.

5526. But have you any improved mode of healing a wound which has resulted from these experiments ?—Yes. For instance, suppose a man stuck his leg through a window by accident, and some glass got in it, you would twenty times more carefully examine that wound to remove the particles of glass with our present knowledge of reflex action than you would have done before.

5527. (*Mr. Huxley.*) Are there not some very remarkable cases of epilepsy arising from local causes of that kind ?—Yes; and which are entirely cured in that way. So that it is essentially therapeutic. If I went into therapeutics as connected with the functions of the nerves I should have to extend my remarks to the widest extent; I do not know where they would stop. Our knowledge on this is all due to experiments on living creatures, and could not have been gained otherwise, but they were not attended with great suffering.

5528. (*Mr. Hutton.*) What was the nature of the therapeutic remedies discovered ?—I have mentioned removing the cause of irritation; a worm in a boy's intestines for example; a spicula on a bone; and so on; cases of people liable to asthma by reflex irritation; the examples are of the widest kind. Then our present theories of inflammation which is the monster fact of disease, have been elucidated more by experiments on animals than in any other way.

5529. But what remedies have been discovered by such experiments ?—We must first know the causes and then the remedies. We have learned that inflammatory action in a very large number of cases is due to disturbed nerve functions; and therefore, instead of treating inflammatory action by antiphlogistic methods, we have learned to support the nervous system, and our patients have recovered. That is therapeutics of the very highest kind, and that has been the great fact of modern therapeutics. Then with regard to tubercle—there are some very curious facts now coming to light about tubercle and the tuberculous condition through experiments on living animals. I do not say at present our therapeutics are much, but there are lines of experiment which seem to promise great help in therapeutics. Some wounds or scrofulous glands which have hitherto been considered rather as a relief to the system and even promoted, there seems reason to think may become seats from which the semina of disease may spread; and if it should so turn out, we may be able to stop many of the tuberculous affections in their bud. I do not say we shall, but still there is a line which seems to be opening in that way by experiments on living animals. Then again the whole theory of vaccination came from experiments on living animals. It is true that Jenner was taught vaccination through the people who took cow-pox from the cows, but we did not know all it meant. By Mr. Ceeley's experiments on animals, by re-vaccination from the human subject, we learnt the real bearing of vaccination, and vaccination is highly therapeutic. It has saved more lives I believe than any other known fact.

5530. (*Chairman.*) I think I remember hearing you once say at the London University that it had saved more lives than all the other discoveries put together ?—It has been put thus;—that the wars of Napoleon were very destructive, but that the discovery of vaccination, which was about that time, saved more lives than his wars destroyed.

5531. Was it by you that that was stated ?—No.

5532. But you adopt it ?—I adopt it entirely.

5533. (*Mr. Hutton.*) Have you ever suggested that certain surgical modifications of the living body might be made which might be transmitted to future generations, and might really improve the organization of the body permanently ?—No; I will explain what I did say, though it did not merit the name of a suggestion, and it was rather meant of lightness than of gravity.

5534. Was it not said to students ?—No. I was President of the Clinical Society, and it was said to a number of members of my profession, and not to students; but even if it had been said to students I should be quite prepared to maintain that science may hereafter show that in our bodies there may be superfluous parts, relicta of ancestral relations, which linger in us, and which (though I do not know them now) may hereafter be found to be useless, and that it is a conceivable object of science to find them out, and it might even be a conceivable object of practice to remove them.

5535. Would you justify experiments upon living animals for investigations of that description ?—I should not say that, because I do not think we are ripe enough for such inquiries; but we may become ripe enough hereafter.

5536. Do you point to the spleen, or what kind of redundant organ ?—As one example the prepuce is considered to be redundant, and its removal useful.

5537. (*Mr. Huxley.*) The teeth which are present in the jaws of the fœtal whale is a fact of the class to which you refer, is it not ?—Yes.

5538. (*Mr. Hutton.*) Is it borne out that modifications caused by these surgical operations are transmitted to future generations ?—I did not affirm they were; but what I hinted was this: Pointing to my friends the surgeons, I said, "Should advancing

Sir W. W. Gull, Bart., M.D.

6 Nov. 1875.

"knowledge show that we have superfluous parts or "organs, and especially if these are liable to disease, "what a land of promise for operations!" But that was merely hypothetical; it was no real suggestion that the surgeon was now to be called in.

5539. It was a joke, was it?—No, indeed it was not a joke. I should say it was an anticipation.

5540. (*Chairman.*) You would rather say it was leviore plectro?—Yes.

5541. (*Mr. Huxley.*) But if you were disposed to argue the case you would have such facts as those relating to the hereditary transmission of the effects of injury, recently brought forward by Brown-Séquard to back you; there is a basis of argumentation for you to go upon there?—Yes, but I did not think the thing was ripe for assertion.

5542. (*Mr. Hutton.*) You would not justify experiments on living animals for a hypothesis so crude as that?—Certainly not; I should not perform experiments at the moment for such a hypothesis, nor should I recommend others to do so.

5543. (*Mr. Huxley.*) But there really is no subject at the present time of greater importance in Biological science than hereditary transmission, is there?—It is most important.

5544. And I presume that if a competent person thought it desirable to perform experiments on hereditary transmission, you would not say that it was wanton conduct?—Certainly not.

5545. (*Mr. Hutton.*) As regards remedial drugs, are there many which you could enumerate which have been discovered by these processes?—I am sorry to say that I am not a great believer in drugs.

5546. But there are some drugs, such as quinine and others, which are useful, but which have not been so discovered?—Of course I do not think that all knowledge is obtained by vivisection.

The witness withdrew.

Mr. G. R. Jesse.

MR. GEORGE RICHARD JESSE recalled and further examined.

5551. (*Chairman.*) When we adjourned the other day, there had not been time for you to finish your statement. Will you be so good as to proceed with it now?—With regard to the list which I was then requested to furnish of the subscribers to the Society for the Abolition of Vivisection, I may state that I am having it prepared. In regard to Mr. E. C. May's letter, which the Commission, I think, demurred to printing in the Appendix, on the score that he being alive, he ought to give evidence himself, I have communicated with him, and he tells me that he has written to the Commissioners to state respectfully that his health totally precludes him from coming here. Under those circumstances, I presume that you will receive the letter and print it.

5552. At all events the Commission cannot receive it from you. Will you please proceed with your statement?—Your decision has quite taken the Society by surprise. We thought, and doubtless correctly, judging from the copy of the Royal Commission on Vivisection, that you had the power to do that; as it says, "To call for, have access to, and "examine all such books, documents, and papers as "may afford the fullest information on the subject, "and to inquire of and concerning the premises by "all other lawful ways and means whatsoever." I merely mention that lest you should have forgotten it.

5553. Will you have the goodness to proceed with your statement?—Certainly, having done all that I can upon that point. Then I think the Commission also objected to allow me to read even a passage from the works of Chalmers; is that so?

5554. It is so?—I understood that that was on the ground that I could not state in what portion of his works it occurred; but one of our Society has been to the British Museum, and I have this morning received the particulars.

5555. What you were told the other day was that if you would have the goodness to put in the reference it was open to you to do so. As I understand, you were not able then to put in the reference, but you are now?—I am.

5556. If you will be so good as to put in the reference we will take notice of it?—The extract is from a sermon by Thomas Chalmers, D.D., published in Edinburgh, March 5th, 1826. I should have thought that a Scotch divine might have been heard against Scotch vivisectors. The sermon is published in a separate volume, second edition, published by Chalmers and Collins, Glasgow, 1826. Then the Society wishes to express most respectfully its regret that it should have been thought necessary to issue a Royal Commission on this subject, inasmuch as torturing animals is contrary to the existing law; and the Society most respectfully wishes to submit that what is required on this question at present, is to enforce the existing law of the land, which is this: the Act 12th and 13th Victoria, chapter 92, passed August 1st, 1849, entitled "An Act for the more "effectual prevention of cruelty to animals." Section 1 repeals 5 and 6 William the Fourth, chapter 59, and 7 William the Fourth and 1 Victoria, chapter 66. Section 2 is, "And be it enacted, that if any person "shall cruelly beat, ill-treat, over-drive, abuse, or "torture, or cause or procure to be cruelly beaten, "ill-treated, over-driven, abused, or tortured any "animal, every such offender shall for every such "offence forfeit and pay a penalty not exceeding 5*l*." There is more in the Act, but that I think is all that it is necessary for me to read. The Society has received very numerous letters from various parts of the kingdom, and from abroad, even I think as far as Peru, expressing great feeling upon the subject, and the very strongest indignation which language can express in regard to the practice of vivisectors. It would take up too much of the time of the Commission, I suppose, (though I do not know for certain about that, to read these documents; but I should like to read one that I received only the day before yesterday, and which may be taken as a sample of many more. Of course we think, and I believe the public will think, these letters very important on this question; because they express the sentiments of a great number of people of education and rank.

The witness withdrew, and the Commission deliberated.

After a short time the witness was again called in.

5557. (*Chairman.*) You have offered us in evidence a letter which we understand comes from Peru?—No; I said we had had letters even from as far as Peru.

5558. What is the letter that you wish to read to the Commission?—It is a letter on the subject of vivisection.

5559. From whom?—From a clergyman who was educated as a physician; in fact, he is a physician too.

5560. Where does he live?—In Devonshire.

5561. Then the same principle which prevents our receiving Mr. May's letter will prevent our receiving any other letter addressed to you by somebody who is not here to be examined by us.

(*Witness.*) That applies to all letters which have been received, doubtless, by the association on the subject of vivisection; very good, I am sorry to hear it.

(*Chairman.*) There are some limits to all things. When a decision is communicated to you by the Commission will you be good enough to accept it, and not to argue it?

(*Witness.*) There are limits to all things. I beg leave to state that I have come here at the request of the Commissioners, and that I represent a society. I

Mr. G. R. Jesse.

6 Nov. 1875.

beg leave to say also that when I was here on a previous occasion there were marks of disrespect from one end of the table which I did not think it worth my while then to notice, but as I have been spoken to in this manner, I beg leave to say that I am sorry that any person appointed by Her Majesty should behave in that way to a witness.

(*Chairman.*) Will you have the kindness to leave us to ourselves for a little while?

The witness then withdrew, and after a short time was again called in.

5562. (*Chairman.*) I am desired by every member of the Commission who is here present to disclaim all intention of having shown any mark of disrespect to you upon the former occasion, and I am sure that I may say the same with regard to any colleague who may have been then present, and may not be present now. Now I have to ask you whether you withdraw that imputation?—I stated my belief at the time. I felt confident of it. I thought it even attracted your own observation. May I ask if it is so? Did anything of the kind attract your observation on a previous occasion?

5563. I have told you on the part of all my colleagues here present that they individually disclaim any such intention, and I ask you, therefore, whether you withdraw the imputation?—Under those circumstances, I am quite ready to say that I am glad to find that I was mistaken.

5564. Now will you proceed with your statement?—"Human Physiology, by John Elliotson, M.D., " Cantab, F.R.S., Fellow of the Royal College of " Physicians, President of the Phrenological Society, " late Professor of Medicine in University College, " London, and Physician to University College " Hospital, formerly Physician to St. Thomas's " Hospital, and President of the Royal Medical " Society of Edinburgh, &c. &c. &c." "London, " Longman, and Company, 1840" (that is enough to enable you to identify the book). On page 448 I read:

"I will not presume . . . .
. . . . the French Institute in 1826."

Then at page 428 there is this:

"Dr. Magendie, who cut living animals here and there with no definite object, but just to see what would happen, informs us that," and so on.

Then on page 429:—"If ever he amused himself by sticking pins in the chorda oblongata of pigeons, the birds thus ornamented by him would walk and fly backwards for above a month!"

On page 465:—"Numerous as have been Dr. Magendie's physiological errors, humbly as I estimate his knowledge and reasoning powers, and much as I abhor his cruelty to brutes," and so on.

Then on page 423, "See Gall, l.c., 8vo., t. vi., p. 210. From page 178 to 288 are excellent remarks upon the unsatisfactory nature of such experiments as have been made by Fleurens, Rolando, &c., &c. See also 4to., vol. iii, p. 56, and 8vo., t. iii, p. 379 sqq. The first three-quarters of the 6th volume should be read by all who are acquainted with the writings of these experimenters, or of Tiedemann, Rudolphi, Serres, &c., upon the brain. They will find these writers less meritorious than they imagined."

Then, on page 424, "Where is the anatomist or physiologist who precisely knows all the origins, the whole extent, all the ramifications, all the connections of an organ? You remove the cerebellum, at the same moment you severely injure the medulla oblongata and spinalis, you injure the tuber annulare you injure the tubercula quadrigemina; consequently, your results relate not merely to all these parts, but to all those which communicate with them, either directly or indirectly. You think you have insulated the tubercles, but these tubercles have connections with the corpora olivaria, the medulla oblongata, the cerebellum, the sense of vision, and many convolutions; the thalami, optici, the corpora striata, are connected below with the crura cerebri, the tuber annulare, the medulla oblongata, the pyramids, and the spinal marrow; above, with all the cerebral membrane, all the convolutions, the non-fibrous grey substance of their surface, with the different commissures, as the anterior commissure, the great commissure or corpus callosum; with the fornix, the septum lucidum. Thus there does not exist a cerebral part which we do not know to have numerous connections with other parts. I do not except even the corpora mammilaria, the pineal gland, the infundibulum, &c. The connections yet unknown are unquestionably still more numerous. (Gall, l.c., p. 240, sqq.) Sir C. Bell has lately imitated Gall in objecting to vivisections as a means of discovery. Gall's nature was most tender. He had a horror of inflicting pain upon poor brutes, and would allow Dr. Magendie to be little more than a canicide. He always kept birds and dogs in his house at Paris, and I have seen him kiss his horses on alighting from his carriage at his country house, and then stand to receive the caresses of several immense bloodhounds which put their fore legs upon his shoulders. (See his glowing remarks on cruelty to brutes, l.c., 4to., vol. iv., p. 196, 8vo., t. v., p. 259, sq.)."

Then on page 426 it goes on to say: "Hence the contradictory and strange observations and inferences of most experimenters on the brain of living brutes." And on page 427: "In opposition to M. Fleurens, MM. Fouville and Pinel Grand-Champs ascribe to the cerebellum the function of sensation. M. Fleurens, after removing the cerebrum, declared all sensation and volition to be lost. M. Bouillaud found animals so deprived give signs of pain, and exert will in endeavouring to escape (Dr. Magendie's Journal, t. x. p. 36 sqq.)."

The society's object in bringing forward some of these works is not only to show the cruelties perpetrated upon our weaker fellow creatures, commonly termed animals, but to show the demoralising effects upon the minds of those who perpetrate them, and which, of course, must tend to spread through society, and particularly when, as now it appears, that these things are to be taught to boys and girls. Now I am going to quote here a man of the first eminence as a veterinary surgeon. The book from which I take the quotation is "The Obligation and Extent of Humanity to Brutes, principally considered with reference to the Domesticated Animals, by M. Youatt, author of 'The Horse,' 'Cattle,' and 'Sheep,' Editor of 'The Veterinarian,'" and so on, published by Longman and Co., 1839, London, and this is on the title page—

'The heart . . . .
. . . . his own.'—
Cowper.

At page 200 I find this:

"'It is,' says Dr. Crampton, ...
. . . . by the very roots."

Then on page 202, "In a northern journal, the Phrenological Magazine, No. 29, are recorded a series of abominable experiments in illustration of the science of phrenology, and to determine the supposed functions of the different parts of the brain. They are so outrageously cruel that they ought not to have been tolerated in any civilized country, much less in the university of modern Athens. 'One experiment consisted in the entire removal of the cerebral lobes from a pigeon; the paring away of the cortical substance from the convex surface of the brain of a second, and of the central hemispheres of a third.' These three pigeons were then coolly and deliberately watched till the moment of their deaths, in order that this brute, rather than a philosopher, might ascertain precisely how long an animal, under such circumstances, retains its power of intelligence, and its faculty of recognising external objects; and also how many acts it was capable of performing, which display any determined end or motive. A hen was deprived of the anterior part of the brain. What was the result of this experiment? The poor fowl not

Mr. G. R. Jesse.

6 Nov. 1875.

having the use of its faculties, as before the injury was inflicted, after being hunted from place to place, attacked by other fowls, thrown from various heights, exposed to violent rain, and to the heat of a kitchen fire, and burnt by hot irons, died in consequence of another experiment. A young dog was selected 'which possessed the reputation of being lively, docile, and intelligent.' And for what purpose? To have 'a thick gimlet forced into the anterior lobes of its brain;' and then to be watched, in order to discover how he will 'eat, drink, and walk;' to have burning irons forced into each anterior lobe; to be pinched occasionally, to ascertain how much feeling he has left, and to have other injuries inflicted upon him, until, on the sixth day he dies. Soon after this, another 'young, lively, docile, and intelligent dog' was selected. The anterior part of the brain of this animal was also transfixed, and his various agonies were closely and minutely watched and recorded. Those words 'watched and recorded' are in italics. 'Water was poured down his throat; camphor was administered. When menaced he crouched as if to implore mercy, and uttered cries which nothing could repress. When menaces were succeeded by blows, he lay down in a supplicating posture and whined. He burnt and scalded his muzzle, lips, and feet by attempting to eat food which was purposely placed before him just taken from the fire.' 'Some days afterwards,' those three words being in italics, 'I led it,' says the miscreant, 'to the river, and regardless of its terror, threw it in. On this occasion it quickly swam on shore and returned to the house.' The poor tortured animal 'still manifesting docility in coming, when after caressing it, we called upon it in a tone of kindness; or if we had menaced, beat, or called upon it in vain, in going away holding down its head and tail, and crouching down as if in the act of supplication. Its eyes became animated, its ears were erected on the slightest noise; but otherwise it had a look of imbecility.' The experiments lasted during 16 days; and, adds M. Bouilland in capital letters, 'It was sacrificed in the performance of a new experiment.' We do not believe that the records of any age contain atrocities more infamous than these. The new Act of the 5th and 6th William IV., surely extends to barbarities like these. We trust that similar exhibitions will never be attempted in any part of the United Kingdom; or if they are, and wherever the disgraceful scene may be enacted, we trust that some persons may be found humane and courageous enough to summon the offender to the tribunal not only of public opinion but of common laws."

This is what the Society at the present moment is endeavouring to do at Edinburgh in regard to Professor Rutherford. We have placed the matter in the hands of our solicitor with regard to experiments of his lately published in the British Medical Journal. On page 20 occurs this quotation; it is from Charles Bell, no doubt Sir Charles. "For my own part I cannot believe that Providence should intend that the secrets of nature are to be discovered by the means of cruelty; and I am sure that those who are guilty of protracted cruelties do not possess minds capable of appreciating the laws of nature."

The society thinks that it is important to show the nature of some of these creatures who are tortured in this manner. You hear some people say that animals have not minds; others deny them immortality, though the latter is certainly what no man can know; and Butler, in his Analogy, says that what applies to the immortality of man applies also to them; and men who have studied the subject know that men of the first calibre of mind (Locke for example) have held the opinion that they have minds, and some believe that they are immortal.

Then on page 45, "My own experience," so this is not only recorded by Youatt, a man of the first eminence in his occupation——

5565. **Are you going to show us that Mr. Youatt's opinions are in favour of the immortality of animals?**—No, not that; but I am going to show here that the intellect and moral qualities of these creatures are such that that consideration alone ought to prevent them from being treated in such a way. That is all. Of course I am not going into an abstract question of that sort.

"My own experience . . . .
. . . . admiration and gratitude."

The Quarterly Review, No. 170, September 1849, at page 390, contains the following: "It was a desire
. . . . in our own day."

I am now about to quote from "Dogs: Their Management; being a new plan of treating the animal, based upon a consideration of his natural temperament, illustrated by numerous woodcuts depicting the character and position of the dog when suffering disease, by Edward Mayhew, M.R.C.V.S. author of 'The Horse's Mouth, showing the Age by the Teeth,' editor of 'Blaine's Veterinary Art,' &c. &c., London, George Routledge and Co., 1858"—On page 163 he says:

"The French have . . . .
. . . . recoil with disgust."

Then on page 73, "The mouth of . . . .
. . . . destined to be its food."

I next quote from "The Life of Sir Astley Cooper, Bart., by Bransby Blake Cooper, Esq., F.R.S., London: John W. Parker, 1843. At page 200 of the first volume I find this:

"Dr. Rools of Kingston . . . .
. . . . the human structure."

Then at page 334 you will find this: "It was not . . . . this scientific receptacle."

We read that to show how this tends to demoralise society. Here were the servants of this surgeon; he made thieves of them; they went and stole dogs for him, taking other people's property. There is another extract in that same volume which I might read, but I think I should only take up your time by reading it; it backs up the other, but I do not think it requires backing up; it can stand by itself. On page 443 of the second volume there is this note:

"His investigations on . . . .
. . . . of the brain."

I conceive from that Sir Astley was afraid of the accusation, not of the cruelty.

I shall now quote from "Canine Pathology, or a Description of the Diseases of Dogs," &c., by Delabere Blaine, London, T. and T. Boosey, Old Broad Street, Royal Exchange, W. Simpkin and R. Marshall, Stationers' Hall Court, Ludgate Street, 1832, third edition. Perhaps I ought to mention that Blaine is, I believe, from what I have heard from veterinarians, also from what I have seen of his books myself, but judging principally from what other veterinarians say of him, the most distinguished veterinarian that this country or any other probably ever produced. He says in regard to mineral poisons, at page 182, "Those who wish for further information relative to the effects produced on dogs by various poisonous agents, may consult Abbé Fontana, Orfila, Mr. Brodie" (the late Sir Benjamin I believe), "&c. &c., who have sacrificed more dogs in experimental inquiry than humanity dares to think of, though science might demand it."

At page 35 there is this passage, "I have thus far
. . . . can be aware of."

I will now read from a "Memoir of George Wilson, M.D., F.R.S.E., Regius Professor of Technology in the University of Edinburgh, and Director of the Industrial Museum of Scotland, by his sister, Jessie Aitken Wilson. Edinburgh: Edmonston and Douglas, 88, Princes Street, and Macmillan and Co., London and Cambridge, 1860." On page 340 I read: "It was at . . . . do as he did."

Then on page 347, speaking of Dr. Wilson, it says: "It is seldom . . . . a human heart."

Mr. G. R. Jesse.

6 Nov. 1875.

In speaking of the life which he wrote of the late Dr. John Reid, of St. Andrews, on page 344, there is this passage: "The great matter . . . . Christianity upon them."

The next quotations are from "Physiological, Anatomical, and Pathological Researches, by John Reid, M.D., Fellow of the Royal College of Physicians of Edinburgh; Chandos Professor of Anatomy and Medicine in the University of St. Andrews, &c., &c., Edinburgh: Sutherland and Knox. London: Simpkin, Marshall, and Co., and Samuel Highley, 1848." The first passage will show how contradictory the opinions of vivisectors are. One seems to lay down a theory by experiments on animals, and then others disprove it. Nobody can wade through (really that is what it has been to me) the works of these men without being forcibly struck by that; and really the want of intellect displayed by these men strikes one, the obtuseness and want of perception.
